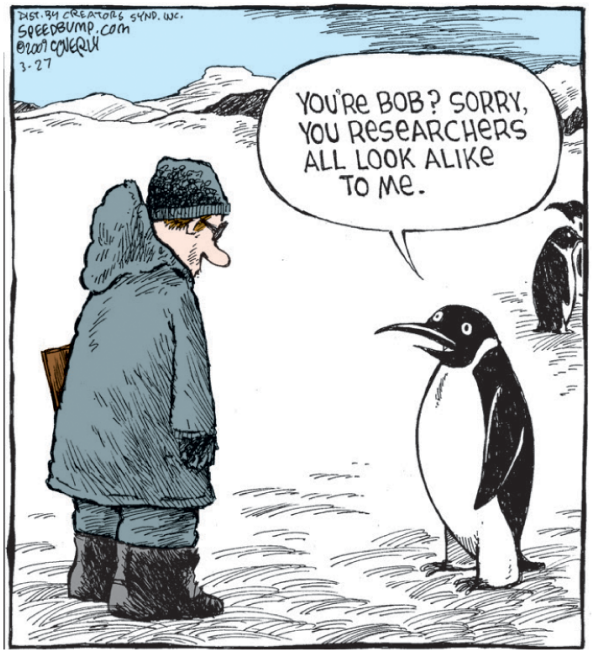
Evidence for the scapegoat theory comes in two forms: (1) *Social trends*: Economically frustrated people often express heightened prejudice, and during economic downturns, racial prejudice intensifies (Bianchi et al., 2018); and (2) *Experiments*: Temporarily



frustrating people intensifies their prejudice. Researchers have found that students who experience failure or are made to feel insecure often restore their self-esteem by disparaging a rival school or another person (Cialdini & Richardson, 1980; Crocker et al., 1987). Denigrating others may boost our own sense of status, which explains why a rival's misfortune sometimes provides a twinge of pleasure. (The German language has a word—*schadenfreude*—for this secret joy that we sometimes take in another's failure.) By contrast, those made to feel loved and supported become more open to and accepting of others who differ (Mikulincer & Shaver, 2001).

"The misfortunes of others are the taste of honey." — Japanese saying

Cognitive Shortcuts

Stereotyped beliefs are a by-product of how we cognitively simplify the world. To help understand the world around us, we frequently form categories. Chemists categorize molecules as organic and inorganic. Therapists categorize psychological disorders. We all categorize people by gender, ethnicity, race, age, and many other characteristics—including their warmth and their competence (Fiske, 2018). But when we categorize people into groups, we often stereotype. We recognize how greatly *we* differ from other individuals in *our* groups. But we overestimate the extent to which members of other groups are alike (Bothwell et al., 1989). We perceive *outgroup homogeneity*—uniformity of attitudes, personality, and appearance. Our greater recognition for individual own-race faces—called the **other-race effect** (or *cross-race effect* or *own-race bias*)—emerges during infancy, between 3 and 9 months of age, also a period when babies learn to distinguish the sounds of their language (Anzures et al., 2013; Telzer et al., 2013). Infant brains become attuned to small differences in familiar sounds and faces. (We also have an *own-age bias*—better recognition memory for faces of our own age group [Cronin et al., 2021; Rhodes & Anastasi, 2012]).

© Dave Coverly/speedbump.com

Sometimes, however, people don't fit easily into our racial categories. When that happens, we often assign them to their outgroup identity. Researchers believe this happens because, after learning the features of a familiar racial group, the observer's *selective attention* is drawn to the distinctive features of the less-familiar outgroup. One study illustrated this learned-association effect by showing research participants blended Chinese-White faces (Halberstadt et al., 2011). Compared with participants of Chinese descent, European-descent participants more readily classified ambiguous faces as Chinese (**FIGURE 43.3**). With effort and experience, people get better at recognizing individual faces from another group (Hugenberg et al., 2010; Young et al., 2012).

FIGURE 43.3 Categorizing mixed-race people When research participants quickly classified 104 photos by race, those of European descent more often than those of Chinese descent classified the ambiguous middle two as Chinese (Halberstadt et al., 2011). The actual digital morphing mix is shown beneath each photo.

Remembering Vivid Cases

We also simplify our world by employing *heuristics*—mental shortcuts that enable snap judgments. The *availability heuristic* is the tendency to estimate the frequency of an event by how readily it comes to mind. Vivid cases come to mind easily, so it's no surprise that they feed our stereotypes. In a classic experiment, researchers showed two groups of students lists containing information about 50 men (Rothbart et al., 1978). The first group's list included 10 men arrested for *nonviolent* crimes, such as forgery. The second group's list included 10 men arrested for *violent* crimes, such as assault. Later, both groups were asked how many men on their list had committed *any* sort of crime. The second group overestimated the number. Violent crimes form vivid memories (FIGURE 43.4).

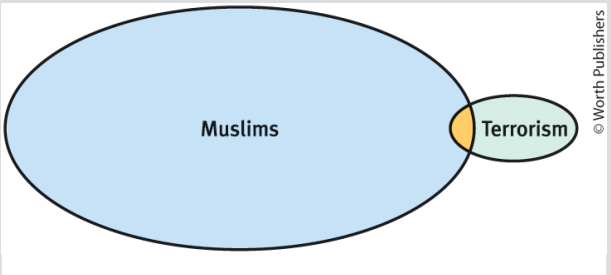


FIGURE 43.4 Vivid cases feed stereotypes
Memorable incidents of global terrorism have fed a stereotype of Muslims as terrorism-prone. Actually, reported a U.S. National Research Council panel on terrorism (which offered this inexact illustration), most terrorists are *not* Muslim.

Victim Blaming

As we noted earlier, people often justify their prejudices by blaming victims. If the world is just, they assume, people must get what they deserve, and believing this makes us feel better (Napier et al., 2020). As one German civilian is said to have remarked when visiting the Bergen-Belsen concentration camp shortly after World War II, "What terrible criminals these prisoners must have been to receive such treatment."

Hindsight bias amplifies victim blaming (Carli & Leonard, 1989). Have you ever heard people say that rape victims, abused spouses, or people with AIDS got what they deserved? In some countries, such as Pakistan, rape victims have been sentenced to severe punishment for violating adultery prohibitions (Mydans, 2002). In one experiment, two groups received a detailed account of a date (Janoff-Bulman et al.,

1985). The first group's account ended with the woman being raped. Members of that group perceived the woman's behavior as at least partly to blame, and in hindsight, they thought, "She should have known better." The second group, given the same account with the rape ending deleted, did not perceive the woman's behavior as inviting rape. In the first group, hindsight bias promoted a blame-the-victim mentality. Blaming the victim reassures people that it couldn't happen to them.

People also tend to justify their culture's social systems (Jost, 2020). We're inclined to see the way things are as the way they ought to be and deserve to be: If people are rich, they must be smart (Hussak & Cimpian, 2015). This natural resistance to change makes it difficult to legislate major social changes, such as health care improvements or climate change policies. Once policies are in place, "system justification" tends to preserve them.

***

If your own gut-check reveals you sometimes have feelings you would rather not have about other people, remember this: It is what we *do* with our feelings that matters. By monitoring our feelings and actions, by replacing old habits with new ones, and by seeking out new friendships, we can work to free ourselves from prejudice.

Retrieval Practice

RP-1 When prejudice causes us to blame an innocent person for a problem, we are using that person as a _____.

ANSWERS IN APPENDIX E

Aggression

LOQ 43-4

How does psychology's definition of *aggression* differ from everyday usage? What biological factors make us more prone to hurt one another?

In psychology, **aggression** is any physical or verbal behavior intended to harm someone, whether done out of hostility or as a calculated means to an end. The assertive, persistent salesperson is not aggressive. Nor is the dentist who makes you wince with pain. But the gossip who passes along a vicious rumor about you, the bully who torments you in person or online, and the attacker who robs you are aggressive. Remember, aggression is a behavior; you must *do* something to act aggressively. Feeling anger or thinking aggressive thoughts don't qualify as aggression.

Aggression emerges from the interaction of biology and experience. For a gun to fire, the trigger must be pulled; with some people, as with hair-trigger guns, it doesn't take much to trip an explosion. What do

you think: Do guns in the home save or take more lives? “Personal safety/protection” is the number one reason people in the United States have given for gun ownership (Swift, 2013). However, firearm ownership can backfire: Guns in the home are much more often used to kill family members or oneself than in self-defense (Kivisto et al., 2019; Stroebe et al., 2017). In 2020, 45,222 Americans died from firearms; nearly 6 in 10 were suicides (CDC, 2022). Over the last half-century more than 1.5 million Americans have suffered nonwar firearm deaths—more than all war deaths in U.S. history (Jacobson, 2015). Compared with people of the same sex, race, age, and neighborhood, those who keep a gun in their home have been twice as likely to be murdered and three times as likely to die by suicide (Anglemyer et al., 2014; Stroebe, 2013). U.S. states with high gun ownership rates also tend to have high gun homicide rates (correlation $r = .82$) (**FIGURE 43.5**). It takes Japan nearly a decade to accumulate as many violent gun deaths as occur in an average U.S. day. More guns → more deaths.

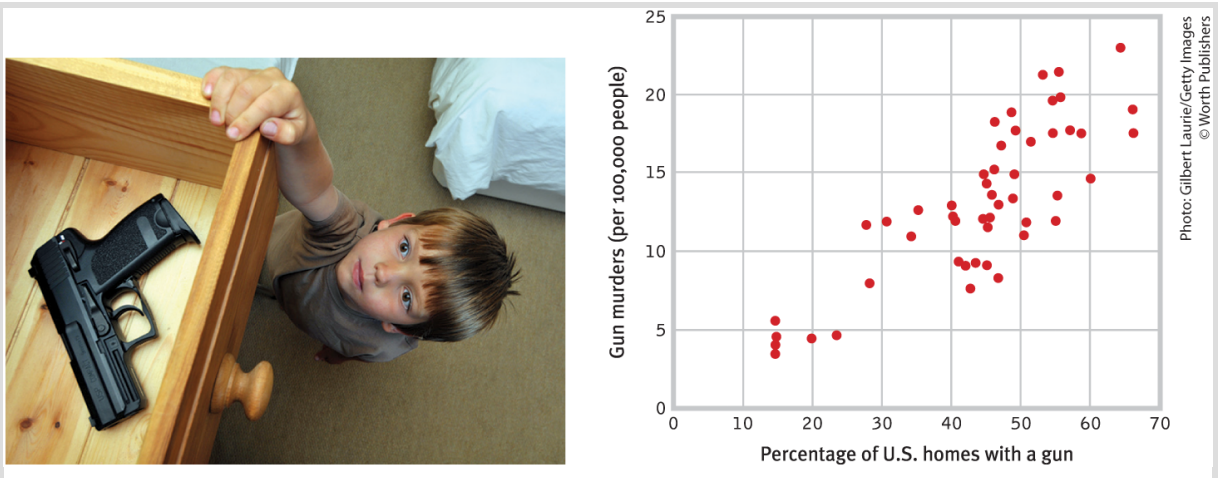

FIGURE 43.5 Gun ownership and murder rates across the 50 U.S. states

Information from CDC (2022) and Learish & Fieldstadt (2022).

In the discussions that follow, we will look first at some biological factors that influence our thresholds for aggressive behavior, then at the psychological factors that pull the trigger.

The Biology of Aggression

Aggression varies too widely from culture to culture, era to era, and person to person to be considered an unlearned instinct. But biology does *influence* aggression. We can look for biological influences at three levels—genetic, neural, and biochemical.

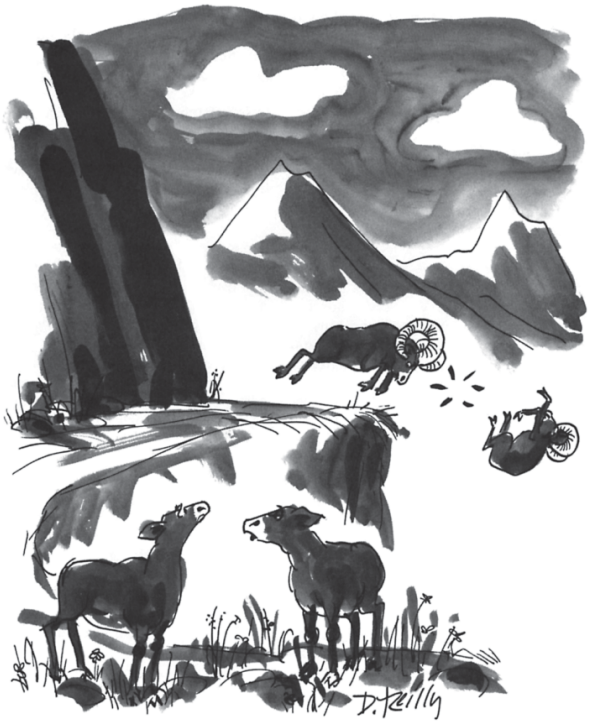
Genetic Influences

Genes influence aggression. Animals have been bred for aggressiveness—sometimes for sport, sometimes for research. The effect of genes also appears in human twin studies (Miles & Carey, 1997; Rowe et al., 1999). If one identical twin admits to "having a violent temper," the other twin will often independently admit the same. Fraternal twins are much less likely to respond similarly.

Researchers continue to search for genetic markers in those who commit violent acts. One is already well known and is carried by half the human race: the Y chromosome. Men are four times more likely than women to commit violent crime (FBI, 2022). Another such

marker is the *monoamine oxidase A (MAOA) gene,* sometimes called the "warrior gene," which is involved in breaking down neurotransmitters such as dopamine and serotonin. People who have low MAOA gene expression tend to behave aggressively when provoked. In one experiment, low (compared with high) MAOA gene carriers gave more unpleasant hot sauce to someone who provoked them (McDermott et al., 2009; Tiihonen et al., 2015).

Neural Influences



There is no one spot in the brain that controls aggression. Aggression is a complex behavior, and it occurs in particular contexts. But animal and human brains have neural systems that, given provocation, will either inhibit or facilitate aggression (Falkner et al., 2016; Fields, 2019). Consider:

- Researchers implanted a radio-controlled electrode in the brain of the domineering leader of a caged monkey colony. The electrode was in an area that, when stimulated, inhibited the leader's aggression. When researchers placed the control button for the electrode in the colony's cage, one small monkey learned to push it every time the boss became threatening.
- A neurosurgeon, seeking to diagnose a disorder, implanted an electrode in the amygdala of a mild-mannered woman. Because the brain has no sensory receptors, she was unable to feel the stimulation. But at the flick of a switch she snarled, "Take my blood pressure. Take it now," then stood up and began to strike the doctor (Moyer, 1983).

- If the frontal lobes are damaged, inactive, disconnected, or not yet fully mature, aggression may be more likely (Amen et al., 1996; Davidson et al., 2000; Raine, 2013). One study of 203 convicted murderers revealed reduced tissue in the frontal lobes (Sajous-Turner et al., 2020).

Biochemical Influences

Our genes engineer our individual nervous systems, which operate electrochemically. The hormone testosterone, for example, circulates in the bloodstream and influences the neural systems that influence aggression. A raging bull becomes a gentle giant when castration reduces its testosterone level. Conversely, when injected with testosterone, gentle, castrated mice become aggressive.

Donald Reilly/Cartoon Stock

"It's a guy thing."

Chris Courteau/AGE Fotostock

A lean, mean fighting machine—the testosterone-laden female hyena The hyena's unusual embryology pumps testosterone into female fetuses. The result is revved-up young female hyenas who seem born to fight.

Humans are less sensitive to hormonal changes. But as men's testosterone levels diminish with age, hormonally charged, aggressive 17-year-olds mature into quieter and gentler 50-year-olds. Drugs that sharply reduce testosterone levels subdue men's aggressive tendencies.

> **"We could avoid two-thirds of all crime simply by putting all able-bodied young men in cryogenic sleep from the age of 12 through 28."** — David T. Lykken, *The Antisocial Personalities,* 1995

Another drug that sometimes circulates in the bloodstream—alcohol—unleashes aggressive responses to frustration. Across police data, prison surveys, and experiments, aggression-prone people are more

likely to drink, and to become violent when intoxicated (White et al., 1993). Alcohol is a disinhibitor—it slows the brain activity that controls judgment and inhibitions. Under its influence, people may interpret ambiguous acts (such as being bumped in a crowd) as provocations and react aggressively (Bègue et al., 2010; Giancola & Corman, 2007). Alcohol consumption has been a factor in 1 in 3 U.S. homicides (Alpert et al., 2022). In countries that have restricted alcohol sales—by reducing alcohol's availability or increasing its price—homicides have dropped (Trangenstein et al., 2021).

Just *thinking* you've imbibed alcohol can increase aggression (Bègue et al., 2009). But so, too, does unknowingly ingesting alcohol slipped into a drink. Thus, alcohol affects aggression both biologically and psychologically (Bushman, 1993; Ito et al., 1996).

Psychological and Social-Cultural Factors in Aggression

LOQ 43-5

What psychological and social-cultural factors may trigger aggressive behavior?

Biological factors influence how easily aggression is triggered. But what psychological and social-cultural factors pull the trigger?

Aversive Events: Hurt People Hurt People

Suffering sometimes builds character. In both laboratory experiments and everyday life, however, those made miserable have often made others miserable (Berkowitz, 1983, 1989; O'Connor et al., 2021). Aversive stimuli—hot temperatures, physical pain, personal insults, foul odors, cigarette smoke, crowding, and a host of others—can evoke hostility. Even hunger can feed anger—making people "hangry" (Bushman et al., 2014). A prime example of this phenomenon is the **frustration-aggression principle**: Frustration creates anger, which can spark aggression.

Teresa Burns Parkhurst/Cartoon Stock

"I just stubbed my toe and need you to come in here so I can scream at you."

The frustration-aggression link was illustrated in an analysis of 27,667 hit-by-pitch Major League Baseball incidents between 1960 and 2004 (Timmerman, 2007). Pitchers were most likely to hit batters when the previous batter had hit a home run, the current batter had hit a home run the last time at bat, or a pitch had hit the pitcher's teammate in the previous half-inning. A separate study found a similar link

between rising temperatures and the number of hit batters (Reifman et al., 1991; see **FIGURE 43.6**). Overheated temperatures → overheated tempers.

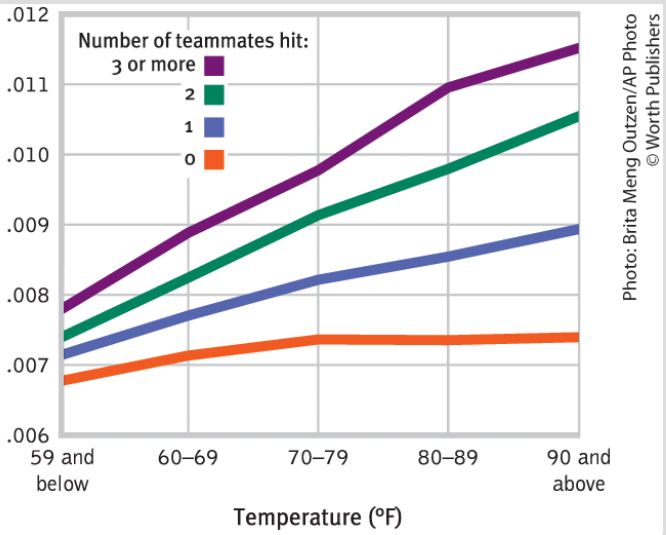


Photo: Brita Meng Outzen/AP Photo © Worth Publishers

FIGURE 43.6 Temperature, tempers, and retaliation Researchers looked for occurrences of batters hit by pitches during 4,566,468 pitcher-batter matchups across 57,293 Major League Baseball games between 1952 and 2009 (Larrick et al., 2011). The probability of a hit batter increased if one or more of the pitcher's teammates had been hit, and also with higher temperatures.

Worldwide, violent crime and spousal abuse rates have been higher during hotter years, seasons, months, and days (Anderson et al., 1997; Heilmann & Kahn, 2019). Studies from archaeology, economics, geography, political science, and psychology converge in finding that throughout human history, higher temperatures have predicted increased individual violence, wars, and revolutions (Hsiang et al., 2013). One projection from available data estimates that global warming of 4 degrees Fahrenheit (about 2 degrees Celsius) could

induce tens of thousands of additional assaults and murders (Miles-Novelo & Anderson, 2022). And that's before the added violence inducements from climate change–related drought, poverty, food insecurity, and migration.

Reinforcement and Modeling

Aggression may naturally follow aversive events, but learning can alter natural reactions. We learn when our behavior is reinforced, and we learn by watching others.

In situations where experience has taught us that aggression pays, we are likely to act aggressively again. Children whose aggression has successfully intimidated other children may become bullies. Animals that have successfully fought to get food or mates become increasingly ferocious. To foster a kinder, gentler world we had best model and reward sensitivity and cooperation from an early age, perhaps by training parents to discipline without modeling violence. Parent-training programs often advise parents to avoid screaming and hitting; instead, they can reward desirable behaviors and frame statements positively (Kazdin, 2018). Rather than say, "If you don't clean your room, you'll be in big trouble," Say "When you clean your room, you can go play."

Different cultures model, reinforce, and evoke different tendencies toward violence. Between 1882 and 1926, lynch mobs in the U.S. state of Georgia murdered 514 people. The best predictors of this collective violence were cultural norms that encouraged and supported

lynching (Ritchey & Rubak, 2018). But other factors also matter: Crime rates have been higher and average happiness lower in times and places marked by a great disparity between rich and poor (Messias et al., 2011; Oishi et al., 2011; Wilkinson & Pickett, 2009). And fathers matter (Triandis, 1994). Even after controlling for parental education, race, income, and teen motherhood, U.S. male youths from father-absent homes have been incarcerated at twice the rate of their peers (Harper & McLanahan, 2004).

Violence can vary by culture within a country. The U.S. South, for example, has long had a "culture of honor." Richard Nisbett and Dov Cohen (1996) analyzed violence among White Americans in southern towns settled by Scots-Irish herders whose tradition encouraged violent response to insult, the use of arms to protect one's flock, and slavery. Compared with their White counterparts in New England towns settled by the more traditionally peaceful Puritan, Quaker, and Dutch farmer-artisans, the cultural descendants of those herders had triple the homicide rates and were more supportive of physically punishing children, of wars, and of uncontrolled gun ownership. Today's culture of honor traditions remain influential, encouraging people to use weapons to defend their honor and to not "back down" (Gul et al., 2021; Lantz & Wenger, 2021).

Media Models for Violence

Television, films, video games, and the internet offer supersized portions of violence. An adolescent boy faced with a real-life challenge may "act like a man"—at least like an action-film man—by

intimidating or eliminating the threat. Media violence teaches us **social scripts**—culturally provided mental files for how to act in certain situations. As more than 100 studies confirm, we sometimes imitate what we've viewed. Watching media depictions of risk-glorifying behaviors (dangerous driving, extreme sports, unprotected sex) increases real-life risk-taking (Fischer et al., 2011). Watching violent behaviors (murder, robbery) can increase real-life aggressiveness (Anderson et al., 2017).

Music lyrics also teach us social scripts. In one study, German university men who listened to woman-hating lyrics poured the hottest chili sauce for a woman to consume. They also recalled more negative feelings and beliefs about women. Listening to man-hating lyrics similarly affected women (Fischer & Greitemeyer, 2006).

How does repeatedly watching pornographic films affect viewers? Just as repeated viewing of on-screen violence helps immunize us to aggression, repeated viewing of pornography—even nonviolent pornography—has made sexual aggression seem less serious (Harris, 1994). In one experiment, undergraduates viewed six brief films weekly for 6 weeks (Zillmann & Bryant, 1984). Some viewed sexually explicit films; others viewed films with no sexual content. Three weeks later, both groups, after reading a report about a man convicted of raping a female hitchhiker, suggested an appropriate prison term. Compared with sentences recommended by the control group, the sex film viewers recommended terms that were half as long. In other studies that explored pornography's effects on aggression toward

relationship partners, pornography consumption predicted both self-reported aggression and participants' willingness to administer laboratory noise blasts to their partner (Lambert et al., 2011; Peter & Valkenburg, 2016). Pornography acts mostly by adding fuel to a fire: It heightens the risk of sexual aggression primarily among aggression-prone men (Malamuth, 2018).

Researchers debate pornography's influence on healthy relationships and sexuality (Grubbs & Kraus, 2021; Zimbardo & Coulombe, 2021). Some experiments suggest that pornography with violent sexual content can increase men's readiness to behave aggressively toward women. As a long-ago statement by 21 social scientists noted, "Pornography that portrays sexual aggression as pleasurable for the victim increases the acceptance of the use of coercion in sexual relations" (Surgeon General, 1986). Analyzing 166 studies involving 125,000 participants, some of today's researchers reached a similar conclusion: "Exposure to sexualized media, especially in combination with violence, has negative effects on women, particularly on what people think about them and how aggressively they treat them" (Burnay et al., 2022).

Do Violent Video Games Teach Social Scripts for Violence?

Experiments worldwide indicate that playing positive games produces positive effects (Greitemeyer & Mügge, 2014; Prot et al., 2014). For example, playing the classic video game *Lemmings,* where a goal was to help others, increased real-life helping. So, might a similar effect

occur after playing games that enact violence? Violent video games became an issue for public debate after teenagers in more than a dozen places seemed to mimic the carnage in the first-person shooter games they had so often played (Anderson, 2004, 2013).

Such incidents of violent mimicry make us wonder: What *are* the effects of actively role-playing aggression? Does it cause people to become less sensitive to violence and more open to violent acts? Amid conflicting findings, nearly 400 studies of 130,000 people offer some answers (Calvert et al., 2017; Kim et al., 2021). Violent video game playing tends to make us less sensitive to cruelty (Arriaga et al., 2015). Video games can prime aggressive thoughts, decrease empathy, and induce us to respond aggressively when provoked. University men who spend the most hours playing violent video games have also tended to be the most physically aggressive (Anderson & Dill, 2000). For example, they more often acknowledged having hit or attacked someone else. More than two dozen longitudinal studies have found that violent video game playing predicts more bullying and physical violence (Prescott et al., 2018; Teng et al., 2022).

Cathal McNaughton/REUTERS/Alamy Stock Photo

Coincidence or cause? In 2011, a Norwegian terrorist killed eight people by bombing government buildings, and then shot and killed 69 people, mostly teens, at a youth camp. Describing his murderous actions, the shooter stirred debate when he commented that "I see MW2 *[Modern Warfare 2]* more as a part of my training-simulation than anything else." Did his violent game playing—and that of the 2022 mass murderer of Uvalde, Texas' elementary school children and teachers—contribute to the violence, or was it a merely coincidental association? Psychologists

explore such questions with experimental research.

In experiments, people who were randomly assigned to play a game involving bloody murders with groaning victims (rather than to play nonviolent games) became more hostile. On a follow-up task, they were more likely to blast intense noise at a fellow student. Studies of young adolescents revealed that those who played a lot of violent video games became more aggressive and saw the world as more hostile (Bushman, 2016; Exelmans et al., 2015; Gentile, 2009). Compared with nongaming kids, they got into more arguments and fights and earned poorer grades. In another experiment, children who played a video game with gun violence (rather than sword violence or no violence) later became more likely to touch, pick up, and pull the trigger on a real (but disabled) gun (Chang & Bushman, 2019).

Ah, but is this merely because naturally hostile kids are drawn to such games (Greitemeyer et al., 2019)? Apparently not. Comparisons of both gamers and nongamers who scored low on hostility measures revealed a difference in the number of fights they reported. Almost 4 in 10 violent-game players had been in fights, compared with only 4 in 100 of the nongaming kids (Anderson, 2004). Some researchers believe that, due partly to the more active participation and rewarded violence of game play, violent video games have even greater effects on aggressive behavior and cognition than do violent TV shows and movies (Anderson & Warburton, 2012).

> **"Research demonstrates a consistent relation between violent video game use and increases in aggressive behavior, aggressive cognitions and aggressive affect, and decreases in prosocial behavior, empathy and sensitivity to aggression."** — American Psychological Association Task Force on Violent Media, 2015

Other researchers are unimpressed by such findings (Ferguson et al., 2020; Markey & Ferguson, 2018). They note that although video game sales have increased, youth violence has declined. They argue that the best studies find minimal effects and that other factors—depression, family violence, peer influence, and a gun-toting culture—better predict aggression. Although some commentators have tried to blame modern mass shootings on violent video games, most researchers agree that they are, at worst, only one modest contributor to social violence (APA, 2019; Mathur & VanderWeele, 2019).

> **"Study finds exposure to violent children causes increased aggression in video game characters."** — *The* [satirical] *Onion,* March 6, 2017

***

To sum up, research reveals biological, psychological, and social-cultural influences on aggressive behavior. Complex behaviors, including violence, have many causes, making any single explanation an oversimplification. Asking what causes violence is therefore like

asking what causes cancer. Those who study the effects of asbestos exposure on cancer rates may remind us that asbestos is indeed a cancer cause, but it is only one among many. Like so much else, aggression is a biopsychosocial phenomenon (FIGURE 43.7).

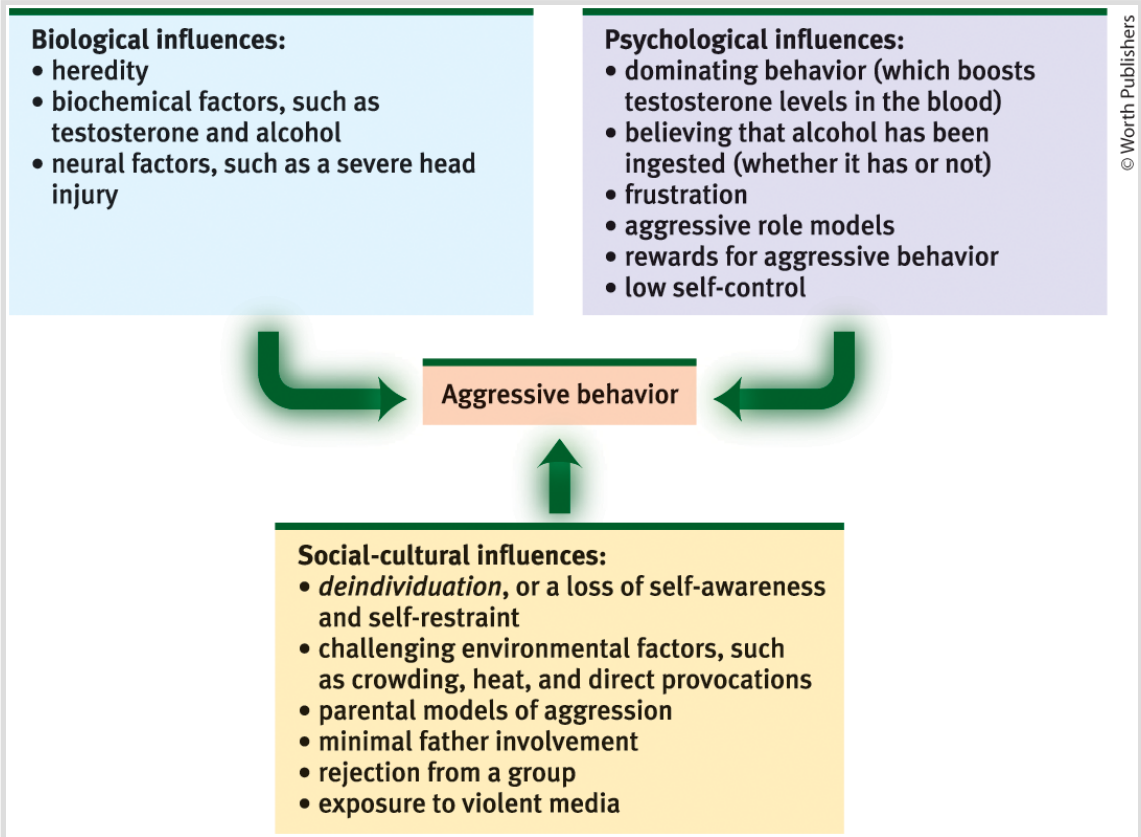

FIGURE 43.7 Biopsychosocial understanding of aggression Because many factors contribute to aggressive behavior, there are many ways to change such behavior, including learning anger management and communication skills, and avoiding violent media and video games.

A happy concluding note: Historical trends suggest that the world is becoming less violent over time (Pinker, 2011, 2018). That people vary across time and place reminds us that environments differ. Yesterday's

plundering Vikings have become today's peace-promoting Scandinavians. Like all behavior, aggression arises from the interaction of persons and situations.

discrimination
implicit bias
just-world phenomenon

ingroup
outgroup
ingroup bias
scapegoat theory
other-race effect
aggression
frustration-aggression principle
social script

Module Test

TestYourself Answer the following questions on your own first, then "show" the answers here, or check your answers in Appendix E.

1. Prejudice toward a group involves negative feelings, a tendency to discriminate, and overly generalized beliefs referred to as _____.

2. If several well-publicized murders are committed by members of a particular group, we may tend to react with fear and suspicion toward all members of that group. In other words, we
   a. blame the victim.
   b. overgeneralize from vivid, memorable cases.
   c. view the world as just.

d. rationalize inequality.

3. The other-race effect occurs when we assume that other groups are _____ (more/less) homogeneous than our own group.

4. Evidence of a biochemical influence on aggression is the finding that
   a. aggressive behavior varies widely from culture to culture.
   b. animals can be bred for aggressiveness.
   c. stimulation of an area of the brain produces aggressive behavior.
   d. a higher-than-average level of the hormone testosterone is associated with violent behavior in males.

5. When those who feel frustrated become angry and aggressive, this is referred to as the _____-_____ _____.

6. Studies show that delinquent young people tend to have parents who used physical force to enforce discipline. This suggests that aggression can be
   a. learned through direct rewards.
   b. triggered by exposure to violent media.
   c. learned through observation of aggressive models.
   d. caused by hormone changes at puberty.

7. A conference of social scientists studying the effects of pornography unanimously agreed that violent pornography

a. has little effect on most viewers.
b. is the primary cause of reported and unreported rapes.
c. leads viewers to be more accepting of coercion in sexual relations.
d. has no effect, other than short-term arousal and entertainment.

8. The aspect of heterosexual pornography that most directly influences men's aggression toward women seems to be the
a. time spent viewing
b. eroticism portrayed.
c. depictions of sexual violence.
d. attractiveness of the actors.

MODULE 44: Prosocial Relations

As social animals—as people who need people—we often approach others not with closed fists, but with open arms. Social psychologists focus not only on the dark side of social relationships, but also on this bright side, by studying *prosocial* behavior—behavior that intends to help or benefit someone. Our positive behaviors toward others are evident from explorations of attraction, altruism and compassion, and peacemaking.

> **"We humans are social beings. We come into the world as the result of others' actions. We survive here in dependence on others. Whether we like it or not, there is hardly a moment of our lives when we do not benefit from others' activities. For this reason, it is hardly surprising that most of our happiness arises in the context of our relationships with others."** — Dalai Lama XIV, *Ethics for the New Millennium,* 2019

Attraction

Pause a moment and think about your relationships. What led to you becoming close friends with someone, or stirred your romantic feelings for someone else? What psychological chemistry binds us together in friendship or love? Social psychology suggests some answers.

The Psychology of Attraction

LOQ 44-1

Why do we befriend or fall in love with some people but not others?

We spend a lot of time thinking about how we can win others' affection and what makes our own affections flourish or fade. Does familiarity breed contempt, or does it amplify affection? Do birds of a feather flock together, or do opposites attract? Is it what's inside that counts, or does physical attractiveness matter, too? To explore these questions, let's consider three ingredients of our liking for one another: proximity, attractiveness, and similarity.

Proximity

Before friendships become close, they must begin. *Proximity*—geographic nearness—is one of friendship's most powerful predictors (Eagle et al., 2009; Nahemow & Lawton, 1975). Proximity can provide opportunities for aggression. But much more often it breeds liking (and sometimes romance) among those who live in the same neighborhood, sit nearby in class, work in the same office, share the same parking lot, or eat in the same dining hall. Look around. Mating starts with meeting.

The power of proximity was illustrated at a "Seeds of Peace" Israeli summer camp (White et al., 2021). The camp sought to reduce

intergroup conflict among outgroup pairs (Jewish and Palestinian teens) with one of three strategies: Share a sleeping bunk, eat at the same table, or attend the same 110-minute dialogue group. Proximity mattered most. Outgroup pairs who shared a sleeping bunk, versus those who did not, were 11 times more likely to become friends. Keep your enemies close and they might become your friends.

Proximity breeds liking partly because of the **mere exposure effect**. Repeated exposure to novel visual stimuli increases our liking for them. By age 3 months, infants prefer photos of the race they most often see—usually their own race (Kelly et al., 2007). Familiarity with a face also makes it look happier (Carr et al., 2017). For our ancestors, this mere exposure effect likely had survival value. What was familiar was generally safe and approachable. What was unfamiliar was more often dangerous and threatening. Evolution may therefore have hard-wired into us the tendency to bond with those who look familiar and to be wary of those who look unfamiliar (Sofer et al., 2015; Zajonc, 1998).

Brendan Beirne/REX/Shutterstock

Familiarity breeds acceptance When this rare white penguin was born in the Sydney, Australia, zoo, his tuxedoed peers ostracized him. Zookeepers thought they would need to dye him black to gain acceptance. But after three weeks of contact, the other penguins came to accept him.

Mere exposure leads to familiarity and thus increases our liking not only for faces, but also for musical selections, geometric figures, Chinese characters (for Chinese language learners), and for the letters of our own name (Moreland & Zajonc, 1982; Nuttin, 1987; Reis et al., 2011; Zajonc, 2001). Mere exposure even increases *unconscious* liking of nonsense syllables—strings of letters presented so quickly our minds don't consciously process them (Van Dessel et al., 2019). So, up to a point (after which the effect wears off), familiarity feeds fondness (Bornstein, 1989, 1999; Montoya et al., 2017). This would come as no surprise to the young Taiwanese man who wrote more than 700 letters

to his girlfriend, urging her to marry him. She did marry—the mail carrier (Steinberg, 1993). No face is more familiar than your own. And that helps explain an interesting finding by Lisa DeBruine (2002, 2004): We like other people when their faces incorporate some morphed features of our own. When McMaster University students played an electronic game with a supposed other player, they were more trusting and cooperative when the other person's image had some of their own facial features morphed into it. In me I trust.

(a) (b)

Which is the real Simu Liu? The mere exposure effect applies even to ourselves. Because the human face is not perfectly symmetrical, the face we see in the mirror is not the same face our friends see. Most of us prefer the familiar mirror image, while our friends like the reverse (Mita et al., 1977). The person actor Simu Liu sees in the mirror each morning is

(b) and that's the photo he would probably prefer over the version that other people see in (a).

Modern Matchmaking

Those who have not found a romantic partner in their immediate proximity may cast a wider net. Millions search for love online. Despite some risks—which, for about half of young U.S. women using online dating sites and apps, include receiving unwanted sexual messages (Anderson et al., 2020; Brown, 2020)—an estimated 77 million people worldwide use online matchmaking services (Statista, 2022).

Online matchmaking expands the pool of potential mates, especially for same-sex couples (Finkel et al., 2012a,b; Rosenfeld et al., 2019). Among couples surveyed in 2017 that had met during the internet age, 39 percent of straight couples and 65 percent of same-sex couples met online (Rosenfeld et al., 2019; see **FIGURE 44.1**). Compared to couples meeting offline, those who meet online more often differ in race or ethnicity (Brown, 2019).

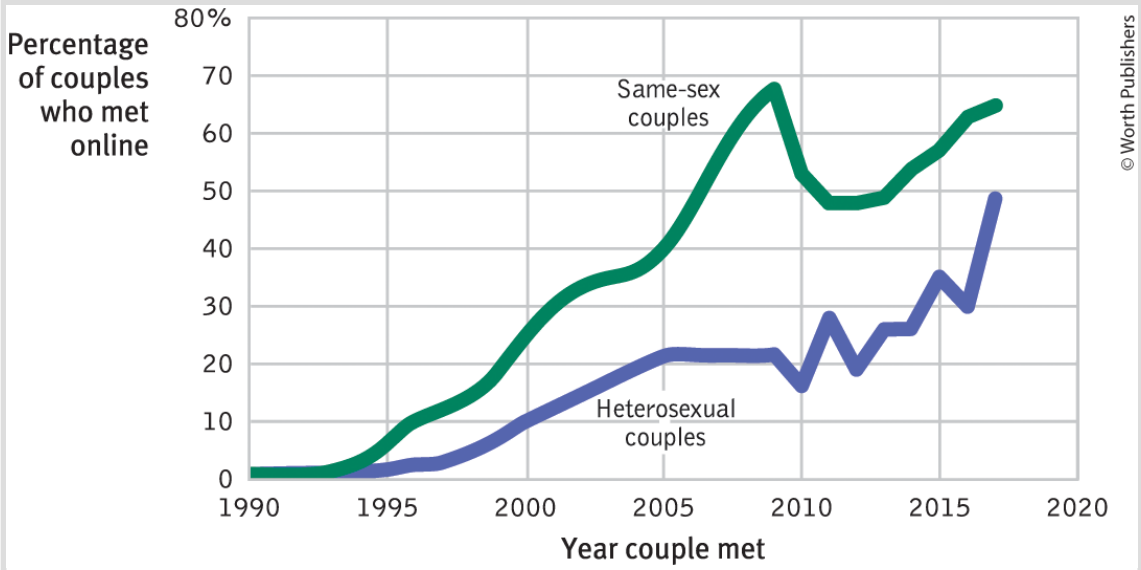

FIGURE 44.1 The changing way we meet our partners The internet's increasing role is clear in U.S. surveys of straight and same-sex couples. (Data from Rosenfeld, 2011; Rosenfeld et al., 2018, 2019)

How effective is the matchmaking? Compared with friendships and romances that began in person, internet-formed relationships are, on average, slightly more likely to last and be satisfying (Bargh & McKenna, 2004; Bargh et al., 2002; Cacioppo et al., 2013). In one study, people disclosed more, with less posturing, to those whom they met online (McKenna et al., 2002). When talking via text or chat with someone for 20 minutes, they felt more liking for that person than they did for someone they had met and talked with face-to-face. This was true even when (unknown to them) it was the same person!

Emily Flake/Cartoon Stock

". . . and if anyone here suspects that the algorithm that put these two together might be flawed, speak now . . ."

Speed dating pushes the search for romance into high gear. At these events, which were pioneered by a matchmaking Jewish rabbi, people meet a succession of prospective partners, either in person or via webcam (Bower, 2009). After a brief 3- to 8-minute conversation, people move on to the next prospect. Those who want to meet again can arrange for future contact. For many participants, a few minutes is enough time to form a feeling about a conversational partner and to register whether the partner likes them (Finkel & Eastwick, 2008).

For researchers, speed dating offers a unique opportunity for studying influences on our first impressions of potential romantic partners. Some findings:

- ***People who fear rejection often elicit rejection.*** After a 3-minute speed date, those who most feared rejection were least often

selected for a follow-up date (McClure & Lydon, 2014).

- ***Given more options, people make more superficial choices.*** When people meet lots of potential partners, they focus on more easily assessed characteristics, such as height and weight (Lenton & Francesconi, 2010).
- ***Similarity is in the eye of the beholder.*** After interacting with dating candidates for 4 minutes each, people's perceived—but not actual—similarity with each person predicted their romantic interest (Tidwell et al., 2013).

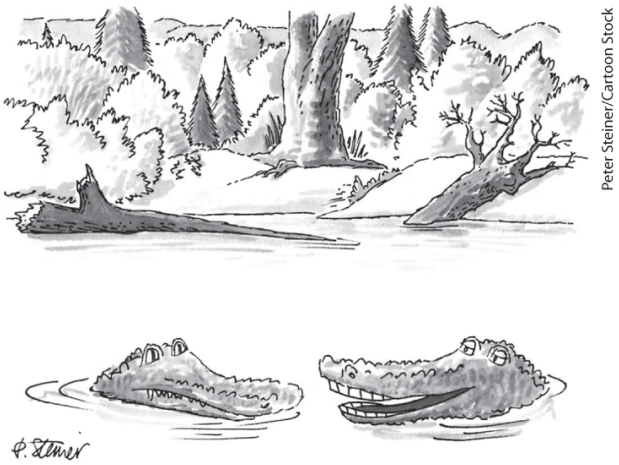
Physical Attractiveness

Once proximity affords us contact, what most affects our first impressions? The person's sincerity? Intelligence? Personality? Hundreds of experiments reveal that it is something more superficial: physical appearance. This finding is unnerving for those of us taught that "beauty is only skin deep" and "appearances can be deceiving."

In one early study, researchers randomly matched new students for heterosexual blind dates in a Welcome Week dance (Walster et al., 1966). Before the dance, the researchers gave each student a battery of personality and aptitude tests, and they rated each student's physical attractiveness. The couples danced and talked for more than 2 hours and then took a brief intermission to rate their dates. What predicted whether they liked each other? Only one thing: appearance. Both the men and the women liked good-looking dates best. Women are more likely than men to say that another's looks don't affect them (Lippa, 2007). But studies show that a man's looks do affect women's behavior

(Eastwick et al., 2014a,b). In speed-dating experiments, attractiveness influences first impressions and liking for men and women (Belot & Francesconi, 2006; Finkel & Eastwick, 2008).

Physical attractiveness also predicts how often people date and how popular they feel. And it affects initial impressions of people's personalities. We perceive attractive people as healthier, happier, more sensitive, more successful, and more socially skilled (Eagly et al., 1991; Fink & Penton-Voak, 2002). We dehumanize unattractive people, especially women (Alaei et al., 2022). This dehumanization can have deadly results: When asked whether they would be willing to kill one person to save five people, participants were more willing to sacrifice the life of an unattractive person.



> **"Personal beauty is a greater recommendation than any letter of introduction."**
> — Aristotle, *Apothegems,* 330 B.C.E.

For those who find the importance of looks unfair, sexist, or unenlightened, three other findings offer some reassurance.

- People's attractiveness is unrelated to their self-esteem and happiness (Diener et al., 1995; Major et al., 1984). And unless we have just compared ourselves with extremely attractive people, few of us (thanks, perhaps, to the mere exposure effect) view ourselves as highly unattractive (Greitemeyer, 2020; Thornton & Moore, 1993).

- Very attractive people are sometimes suspicious that praise for their work may simply be a reaction to their looks. Less attractive people have been more likely to accept praise as sincere (Berscheid, 1981).
- For couples who were friends before lovers—who became romantically involved long after first meeting—looks matter less (Hunt et al., 2015). With slow-cooked love, shared values and interests matter more.

Beauty is also in the eye of the culture. People across the globe have modified their bodies in different ways, driven by cultural ideas of attractiveness. They have pierced and tattooed their bodies, lengthened their necks, bound their feet, artificially lightened or darkened their skin or hair, and bulked up their muscles. They have applied chemicals to rid themselves of unwanted hair or to regrow wanted hair, and used undergarments to change the proportions of waists, hips, and breasts. Cultural ideals also change over time and with context. For women in North America, for example, the ultrathin ideal of the Roaring Twenties gave way to the soft, voluptuous Marilyn Monroe ideal of the 1950s and then to today's more athletic ideal look.

"Cosmetic dentistry changed my life."

Some aspects of sexual attractiveness, however, do cross place and time (Cunningham et al., 2005; Langlois et al., 2000). By providing reproductive clues, bodies influence sexual attraction. As some evolutionary psychologists explain, straight men in cultures worldwide judge romantic partners as more attractive if they have a youthful, fertile appearance (Walter et al., 2020). Straight women feel attracted to men who are healthy- and fertile-looking, but are most attracted to men who seem mature, dominant, and affluent (Feingold, 1990; Gallup & Frederick, 2010; Gangestad et al., 2010). One review reported that straight men may place higher value on physical attractiveness than straight women (Feingold, 1990). Gay and bisexual women have reported a preference for larger body figures (Cohen & Tannenbaum, 2001).

Morsa Images/DigitalVision/Getty Images

What is "attractive"? The answer varies by culture and over time. Yet some adult physical features, such as a healthy appearance and a relatively symmetrical face, seem attractive everywhere. Some people use a photo filter that makes their face symmetrical (as has been applied to the face on the right, above) for social media presentation (Garelick, 2022).

People's attractiveness influences our first impressions: We tend to think that what is beautiful is also good. But we also perceive what is good as beautiful (He et al., 2022). Our feelings color our attractiveness judgments. Imagine two people: One is honest, humorous, and polite. The other is rude, unfair, and abusive. Which one is more attractive? Most people perceive the person with the appealing traits as more physically attractive (Lewandowski et al., 2007). Or imagine being paired with a stranger of the gender you find attractive—someone who listens intently to your self-disclosures. Might you feel a twinge of sexual attraction toward that empathic person? Student volunteers did, in several experiments (Birnbaum & Reis, 2012). People find smiling potential partners more attractive (Mehrabian & Blum, 2018). Those we like we find attractive.

Shakespeare said it in *A Midsummer Night's Dream:* "Love looks not with the eyes, but with the mind." As we see our loved ones

repeatedly, their physical imperfections grow less noticeable and their attractiveness grows more apparent (Beaman & Klentz, 1983; Gross & Crofton, 1977). Come to love someone and watch beauty grow. Love sees loveliness.

Similarity

So, proximity has brought you into contact with someone, and your appearance has made an acceptable first impression. What influences whether you will become friends? As you get to know each other, will the chemistry be better if you are opposites or if you are alike?

It makes a good story—extremely different types liking or loving each other: unlikely friends Frog and Toad in Arnold Lobel's books, unlikely couple Hermione and Ron in the Harry Potter series.

But in many real-life situations, opposites retract (Montoya & Horton, 2013; Oosterhoff et al., 2022; Rosenbaum, 1986). Tall people often find true love with other tall people; short people show a soft spot for other short people (Yengo et al., 2018). Compared with randomly paired people, friends and couples are far more likely to share—and to like those with whom they share—attitudes, beliefs, interests, and even personality traits (and, for that matter, age, religion, race, education, intelligence, smoking behavior, and economic status). Most people's immediate neighbors tend to be from the same political party (Brown & Enos, 2021). As C. S. Lewis (1960) observed, "What draws people to be friends is that they see the same truth."

While there is some evidence that among married, same-sex couples, similarity in personality may not predict long-term happiness (Shiota & Levinson, 2007), for most relationships, the more alike people are, the more their liking endures (Byrne, 1971; Hartl et al., 2015). One journalist was right to suppose that love lasts "when the lovers love many things together, and not merely each other" (Lippmann, 1929).

Similarity attracts; perceived dissimilarity does not.

Proximity, attractiveness, and similarity are not the only determinants of attraction. We also like those who like us. When we believe someone likes us, we feel good and respond to them warmly, which leads them to like us even more (Curtis & Miller, 1986). To be liked is powerfully rewarding. Moreover, there is a *liking gap*: After two

strangers interact, both tend to report liking the other person more than they presume the other liked them. This is good news to remember: Most people immediately like us more than we realize (Boothby et al., 2018; Wolf et al., 2021).

Indeed, all the findings we have considered so far can be explained by a simple *reward theory of attraction:* We will like those whose behavior is rewarding to us, including those who are both able and willing to help us achieve our goals (Montoya & Horton, 2014). When people live or work in close proximity to us, it requires less time and effort to develop the friendship and enjoy its benefits. When people are attractive, they are aesthetically pleasing, and associating with them can be socially rewarding. When people share our views, they reward us by validating our own beliefs.

Romantic Love

LOQ 44-2

How does romantic love typically change as time passes?

Sometimes people move from initial impressions to friendship to the more intense, complex, and mysterious state of new romantic love. If love endures, temporary *passionate love* will mellow into a lingering *companionate love* (Hatfield, 1988; Fehr et al., 2014).

Passionate Love

Passionate love mixes something new with something positive (Aron et al., 2000; Coulter & Malouff, 2013). We intensely desire to be with our partner, and seeing our partner stimulates blood flow to brain regions linked to craving and obsession (Acevedo et al., 2012; Hatfield et al., 2015).

MAURIX/Gamma-Rapho/Getty Images

Love is an ancient thing This 5000- to 6000-year-old "Romeo and Juliet" young couple was unearthed locked in embrace, near Rome.

The *two-factor theory of emotion* can help us understand the intense positive absorption of passionate love (Hatfield, 1988). It assumes that

- emotions have two ingredients—*physical arousal* plus *cognitive appraisal.*
- arousal from any source can enhance one emotion or another, depending on how we interpret and label the arousal.

In one classic experiment, researchers studied straight men crossing two bridges above British Columbia's rocky Capilano River (Dutton & Aron, 1974, 1989). One, a swaying footbridge, was 230 feet (70 meters) above the rocks; the other was low and solid. As the men came off

each bridge, an attractive young woman (working for the researchers) intercepted them and asked them to fill out a short questionnaire. She then offered her phone number in case they wanted to hear more about her project. Far more of the men who had just crossed the high bridge—which left their hearts pounding—accepted the number and later called the woman.

To be revved up and to associate some of that arousal with a desirable person is to feel the pull of passion. So, if you're looking for romance, perhaps take your date to a climbing gym. Adrenaline makes the heart grow fonder. Sexual desire + a growing attachment = passionate love (Berscheid, 2010).

Companionate Love

Although the desire and attachment of romantic love often endure, the intense absorption in the other, the thrill of the romance, the giddy "floating on a cloud" feelings typically fade. Does this mean the French are correct in saying that "love makes the time pass and time makes love pass"? Or can friendship and commitment keep a relationship going after the passion cools?

As love matures, it typically becomes a steadier **companionate love**—a deep, affectionate attachment (Hatfield, 1988). For people worldwide, as relationships mature they evolve: Passion subsides and commitment grows (Sorokowski et al., 2021). Like a passing storm, the flood of passion-facilitating hormones (testosterone, dopamine, adrenaline) subsides. But another hormone, *oxytocin,* remains,

supporting feelings of trust, calmness, and bonding with the mate. This shift from passion to attachment has adaptive value (Reis & Aron, 2008). Passionate love often produces children; companionate love aids children's survival as the parents lose their obsession with each other.

"I think I know where the passion in our marriage has gone."

In the most satisfying marriages, attraction and sexual desire endure, minus the obsession of early romance (Acevedo & Aron, 2009). Recognizing the short duration of obsessive passionate love, some societies deem such feelings an irrational reason for marrying. Better, they say, to seek (or have someone seek for you) a partner with a compatible background and interests. Cultures where people rate love as less important for marriage do have lower divorce rates (Levine et al., 1995).

One key to a gratifying and enduring relationship is **equity.** When equity exists—when both partners receive in proportion to what they give—the chances for sustained and satisfying companionate love are

good (Gray-Little & Burks, 1983; Van Yperen & Buunk, 1990). In one national survey, "sharing household chores" ranked third, after "having shared interests" and a "satisfying sexual relationship," on a list of seven things people associated with successful marriages (Geiger, 2016). As the saying goes, "I like hugs. I like kisses. But what I really love is help with the dishes."

Equity's importance extends beyond marriage. Mutually sharing one's self and possessions, making decisions together, giving and getting emotional support, promoting and caring about each other's welfare—all of these acts are at the core of every type of loving relationship (Sternberg & Grajek, 1984). It's true for lovers, for parent and child, and for close friends.

Sharing includes **self-disclosure**, revealing intimate details about ourselves—our likes and dislikes, our dreams and worries, our proud and shameful moments. "When I am with my friend," noted the Roman statesman Seneca, "methinks I am alone, and as much at liberty to speak anything as to think it." Self-disclosure breeds liking, and liking breeds self-disclosure (Collins & Miller, 1994). As one person reveals a little, the other reciprocates, the first then reveals more, and on and on, as lovers (and friends) move to deeper levels of intimacy (Baumeister & Bratslavsky, 1999).

One experiment marched some student pairs through 45 minutes of increasingly self-disclosing conversation—from "What is the greatest accomplishment of your life?" to "When did you last cry in front of

another person? By yourself?" Other pairs spent the time with small-talk questions, such as "What was your high school like?" (Aron et al., 1997). By the experiment's end, those experiencing the escalating intimacy felt much closer to their conversation partner than did the small-talkers. Likewise, after dating couples spent 45 minutes answering such questions, they felt increased love (Welker et al., 2014).

In addition to equity and self-disclosure, a third key to enduring love is *positive support.* For happy couples in enduring relationships, positive interactions (compliments, touches, laughing) outnumber negative interactions (sarcasm, disapproval, insults) by at least 5 to 1 (Gottman & Gottman, 2022). In the mathematics of love, self-disclosing intimacy + mutually supportive equity = enduring companionate love.

Relationship conflicts are inevitable, but hurtful communications are not. Do we more often express sarcasm or support, scorn or sympathy, sneers or smiles? In romance, a rejection hurts more and for longer than an acceptance pleases (Dobson et al., 2020). For unhappy couples, disagreements, criticisms, and put-downs are routine. It takes multiple compliments to equal the attention-getting and emotion-affecting power of one criticism.

Couples benefit from making space for positive communication. In one experiment, some couples were randomly assigned to once a week spend 15 minutes with their partner writing down "three *good*

things that happened to you as a couple during the week" and noting "why did this good thing happen?" After six weekly repetitions, these couples reported increased satisfaction and intimacy (Boiman-Meshita & Littman-Ovadia, 2021).

RP-4 Two vital components for maintaining *companionate love* are _____ and _____-_____.

ANSWERS IN APPENDIX E

Altruism

LOQ 44-3

What is *altruism?* When are people most—and least—likely to help?

"We are made for goodness," observed South African Archbishop Desmond Tutu (1931–2021). "Why else do we get so outraged by wrong?"

So it seemed during the first two weeks of March, 2021. Outraged by Russia's violence against Ukraine, people from 165 countries booked more than 430,000 nights at Ukrainian Airbnbs, most belonging to

people they did not know (Friedman, 2022). The purchasers had no intention of using the reservation; they simply wanted to donate money to people who were hurting. In the invasion's first two weeks, nearly $400 million in additional donations were made by people from around the world to support Ukrainians (Roohi, 2022).

Among those fleeing Ukraine were cousins Lesia Orshoko and Alona Chugai. On their arrival in Israel, they were welcomed by Sharon Bass, a Jew who owed her existence to the long-ago altruism of the cousins' "righteous Gentile" Ukrainian grandmother, Maria Blyshchik. For 2 years Blyshchik hid Bass's grandmother, Fania Rosenfeld, then a teen, sparing her from the Holocaust that killed her parents and five siblings.

After later relocating to Israel, Fania Rosenfeld Bass would tell the story "over and over to her children and grandchildren, letting them know about the good people who held on to their humanity and quietly rebelled against the horrors of the war" (Greenbaum, 2022). Eight decades later, as war ravaged Ukraine, Sharon Bass reciprocated that heroic goodness by enabling the cousins' escape to Israel and welcoming them into her home. For as long as they wish, she said, her house is their house.

Sharon Bass

Altruism across generations Israeli Sharon Bass (middle) is pictured here with Ukrainian refugees Lesia Orshoki (left) and Alona Chugai (right).

Such acts of **altruism** show that humans are capable of great evil, but also, as we shall see, of great goodness.

Altruism became a major concern of social psychologists after a widely publicized incident. On March 13, 1964, a stalker repeatedly stabbed Kitty Genovese, then raped her as she lay dying outside her Queens, New York, apartment at 3:30 A.M. "Oh, my God, he stabbed me!" Genovese screamed into the early morning stillness. "Please help me!" Windows opened and lights went on as some neighbors heard her screams. Her attacker fled and then returned to stab and rape her again. No one called the police or came to her aid until it was too late.

Bystander Intervention

Newspaper accounts of the murder, which misreported the number of witnesses and their responses to Genovese's cries, triggered public outrage over the bystanders' apparent "apathy" and "indifference." However, social psychologists John Darley and Bibb Latané (1968) attributed bystanders' inaction not to character flaws or moral choices, but to an important situational factor—the presence of others. Given certain circumstances, they suspected, most of us would behave similarly. To paraphrase the French writer Voltaire, we all are guilty of the good we did not do.

After staging emergencies under various conditions, Darley and Latané assembled their findings into a decision scheme: We will help only if the situation enables us first to *notice* the incident, then to *interpret* it as an emergency, and finally to *assume responsibility* for helping (FIGURE 44.2). At each step, the presence of others can turn us away from the path that leads to helping.

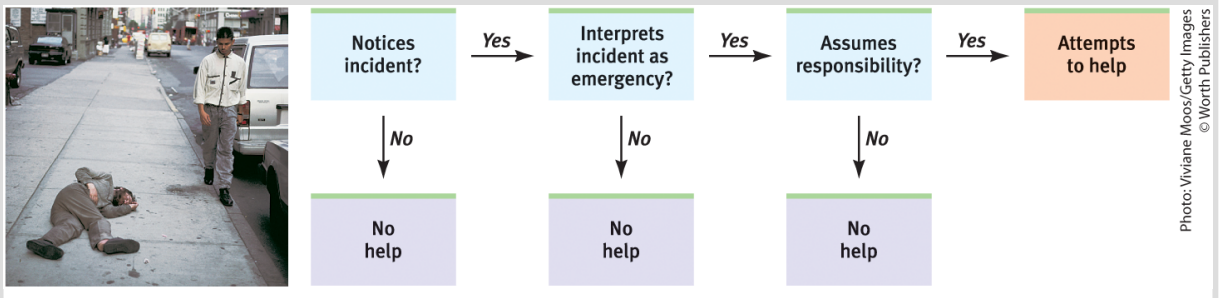

FIGURE 44.2 The decision-making process for bystander intervention (Data from Darley & Latané, 1968.)

One of Darley and Latané's experiments staged a fake emergency as students in separate laboratory rooms took turns talking over an intercom. Only the person whose microphone was switched on could be heard. When his turn came, one student (actually an accomplice) pretended to have an epileptic seizure, and he called for help (Darley & Latané, 1968).

How did the others react? As **FIGURE 44.3** shows, those who believed only they could hear the victim—and therefore thought they alone were responsible for helping him—usually went to his aid. Students who thought others could also hear the victim's cries were more likely to do nothing. When more people shared responsibility for helping—when there was a **diffusion of responsibility**—any single listener was less likely to help. Indeed, inattention and diffused responsibility contribute to "global bystander nonintervention" as millions of far-away people die of hunger, disease, and genocide (Pittinsky & Diamante, 2015).

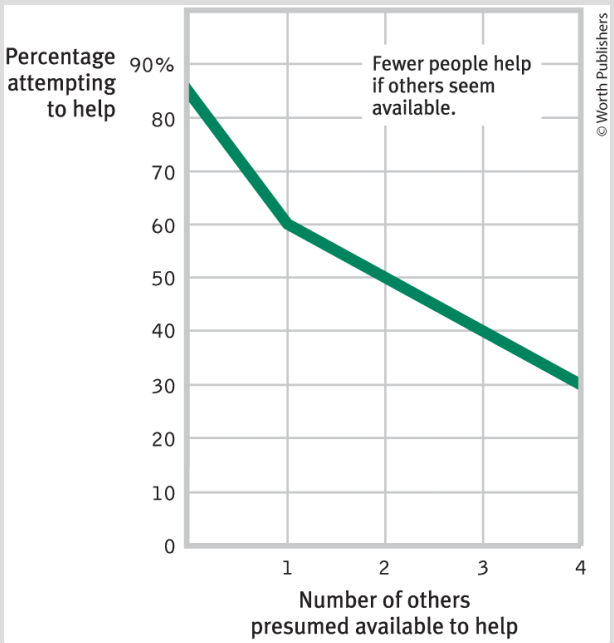

FIGURE 44.3 Responses to a simulated emergency When people thought they alone heard the calls for help from a person they believed to be having an epileptic seizure, they usually helped. But when they thought four others were also hearing the calls, fewer than one-third responded. (Data from Darley & Latané, 1968.)

Hundreds of additional experiments have confirmed this **bystander effect.** For example, researchers and their assistants took 1497 elevator rides in three cities and "accidentally" dropped coins or pencils in front of 4813 fellow passengers (Latané & Dabbs, 1975). When alone with the person in need, 40 percent helped; in the presence of 5 other bystanders, only 20 percent helped.

When reflecting on the bystander research—or on the conformity and obedience experiments in Module 42—it's tempting to think that, unlike many of the participants, we would have responded with moral courage. We may tell ourselves that, unlike so many others who lived before us, we would have taken steps to protect Jews from the Nazi genocide or intervened as George Floyd was slowly killed by a police officer. But research suggests we do not always act according to the better angels of our nature. In experiments, people greatly overestimate the odds of their protesting a sexist remark or a racial slur (Swim & Hyers, 1999).

Although the presence of other bystanders reduces the chance that an individual will offer help, often, people *do* help. In CCTV surveillance of arguments and fights caught on the streets of Amsterdam, Lancaster, and Cape Town, 9 times out of 10 at least one bystander and usually more did something to help (Philpot et al., 2019). Another research team planted 17,303 "lost" wallets in 40 countries, walking into public places such as hotels, post offices, and banks and explaining to a clerk: "I found this on the street around the corner. Someone must have lost it. I'm in a hurry and have to go. Can you please take care of it?" Forty percent of those given cashless wallets alerted the owner. Surprisingly to economists surveyed, those receiving wallets with cash were even *more* likely (51 percent) to help (Cohn et al., 2019).

Observations of behavior in thousands of these situations—relaying an emergency phone call, aiding a stranded motorist, donating blood,

picking up dropped books, contributing money, giving time—show that the odds of our helping someone depend on the characteristics of that person, the situation, and our own internal state. The odds of helping are highest when

- the person appears to need and deserve help.
- the person is in some way similar to us.
- the person is a woman.
- we have just observed someone else being helpful.
- we are not in a hurry.
- we are in a small town or rural area.
- we are feeling guilty.
- we are focused on others and not preoccupied.
- we are in a good mood.

The "good mood" result—that happy people are helpful people—is one of psychology's most consistent findings. As poet Robert Browning (1868) observed, "Oh, make us happy and you make us good!" It doesn't matter how we are cheered. Whether by being made to feel successful and intelligent, by thinking happy thoughts, by finding money, or even by receiving a posthypnotic suggestion, we become more generous and more eager to help (Aknin et al., 2019). Moreover, the world's happiest countries are also countries where people more often volunteer, give money, and even offer organ donations (Rhoads et al., 2021). And if our feeling of elevation follows witnessing or learning of someone else's self-giving deed, our helping will become even more pronounced (Schnall et al., 2010).

So, happiness begets helpfulness. But it's also true that helpfulness breeds happiness (Hui et al., 2020). Helping those in need activates brain areas associated with reward (Harbaugh et al., 2007; Kawamichi et al., 2015). That helps explain a curious finding: People who give money away are happier than those who spend it almost entirely on themselves. In one controlled experiment, researchers gave people money and instructed one group to spend it on themselves, and another group to spend it on others (Aknin et al., 2020). Which group was happiest afterward? It was, indeed, those assigned to the spend-it-on-others condition. Worldwide, people in both rich and developing countries were happier with their lives if they had donated to a charity in the last month (Dunn et al., 2008). You can likely recall a mood boost merely from giving directions to a stranger. *The lesson:* Doing good feels good.

Zinkevych/iStock/Getty Images

Happy to give a dog a bone In an experiment, pet owners who spent money on their pets felt happier than did pet owners who spent money on themselves (White et al., 2022).

ANSWERS IN APPENDIX E

Norms for Helping

LOQ 44-4

How do social exchange theory and social norms explain helping behavior?

Why do we help? One widely held view is that self-interest underlies all human interactions, that our constant goal is to maximize rewards and minimize costs. Accountants call it *cost-benefit analysis.* Philosophers call it *utilitarianism.* Social psychologists call it **social exchange theory.** For example, if you are considering donating blood, you may weigh the costs of doing so (time, discomfort, anxiety) against the benefits (reduced guilt, social approval, good feelings). If the rewards exceed the costs, you will donate blood.

Others believe we help because we have been socialized to do so, through norms that prescribe how we *ought* to behave (Everett et al., 2015). Two such norms are the *reciprocity norm* and the *social-responsibility norm.*

The **reciprocity norm** is the expectation that we should help, not harm, those who have helped us. Those for whom we do favors will often return favors. (Be kind to others and you may elicit future kindness from them.) With similar others, the reciprocity norm motivates us to give (in favors, gifts, or social invitations) about as much as we receive. Sometimes this means "paying it forward": In one experiment people who were treated generously became more likely to be generous to a stranger (Tsvetkova & Macy, 2014). Returning favors feels good, so we tend to find the reciprocity norm a pleasant way to help others (Hein et al., 2016).

The reciprocity norm kicked in after Dave Tally found $3300 in a backpack that an Arizona State University student had misplaced on his way to buy a used car (Lacey, 2010). Tally was homeless at the time, but instead of using the cash for much-needed bike repairs, food, and shelter, he turned the backpack in to the social service agency where he volunteered. To reciprocate Tally's help, the backpack's owner thanked him with a cash reward. Hearing about Tally's selfless deed, dozens of others also sent him money and job offers.

The **social-responsibility norm** is the expectation that we should help those who need our help—such as young children and newcomers—

even if the costs outweigh the benefits. Europeans are most responsive to help sought by the most vulnerable asylum seekers—those, for example, who have been tortured or have no surviving family (Bansak et al., 2016). During the Covid-19 pandemic, many people—despite the risk of infection—cared for the sick, shopped for older neighbors, and donated money to help those in need (Fridman et al., 2022). Many people also responded affirmatively to persuasion that defined mask-wearing as an act of kindness and concern for others (Van Bavel et al., 2020).

Invoking the social-responsibility norm

We're especially likely to respond to requests for help when asked face-to-face, rather than by phone or email (Roghanizad & Bohns, 2022). People often hesitate to ask others to, for example, take their photo at a picturesque place. But experiments show that they underestimate others' willingness to help and underestimate how positively helpers will feel (Zhao et al., 2022). So, when you could use a favor, just ask. More often than you suppose, people—even strangers—will gladly help and feel good about doing so.

Many world religions encourage their followers to practice the social-responsibility norm, and sometimes this leads to prosocial behavior (Henrich, 2020). Between 2006 and 2008, Gallup polls sampled more than 300,000 people across 140 countries, comparing the "highly religious" (who said religion was important to them and who had attended a religious service in the prior week) to those less religious. The highly religious, despite being poorer, were about 50 percent more likely to report having "donated money to a charity in the last month" and to have volunteered time to an organization (Pelham & Crabtree, 2008). New surveys of 8000 Australians and 32,000 New Zealanders replicated this association of religious engagement with volunteerism (Petrovic et al., 2021; Van Tongeren et al., 2021). In more than two dozen "God-priming" studies, merely reminding people of God led them to cheat less and help more (Henrich, 2020).

Denis Poroy/AP Photo

Heroic helping In 2019, when a gunman entered a California synagogue, 60-year-old Lori Gilbert-Kaye was murdered when she selflessly used her body to shield her rabbi. Social psychologists study what prompts people to help.

From Conflict to Peace

Positive social norms encourage generosity and enable group living. But conflicts often divide us. One response to recent conflict- and scarcity-driven migrations has been anti-immigrant nationalism and nativism (favoring native-born citizens over newcomers). Psychologists have wondered: What in the human mind causes destructive conflict? How might a spirit of cooperation replace the perceived threats of social diversity?

Elements of Conflict

LOQ 44-5

How do social traps and mirror-image perceptions fuel social conflict?

To a social psychologist, a **conflict** is a perceived incompatibility of actions, goals, or ideas. The elements of conflict are much the same, whether partners sparring, political groups feuding, or nations at war. In each situation, conflict may seed positive change, or it may be a destructive process that can produce unwanted results. Among the destructive processes are *social traps* and *distorted perceptions*.

Social Traps

In some situations, pursuing our personal interests also supports our collective well-being: A person may choose to get vaccinated for self-

protection from a contagious disease, but their decision means that they are also less likely to pass that disease on to others, and the whole community benefits from it. In other situations, we *harm* our collective well-being by pursuing our personal interests. Such situations are **social traps**.

Researchers have created mini social traps in laboratory games that require two participants to choose between pursuing their immediate self-interest, at others' expense, versus cooperating for mutual benefits. Many real-life situations similarly pit our individual interests against our communal well-being. Individual fish trawlers reasoned that the fish they took would not threaten the species and that if they didn't take them, others would anyway. The result: depleted fish stocks. Anticipating Covid-19-related shutdowns, people bought and hoarded toilet paper, leaving shelves empty for others. Individual car owners and homeowners reason, "Electric cars are more expensive. Besides, the fuel that I burn in my one car doesn't noticeably add to the greenhouse gases." When enough people reason similarly, the collective result threatens disaster—climate change, rising seas, and more extreme weather.

Jeff J Mitchell/Getty Images

Not in my ocean! Many people support alternative energy sources, including wind turbines. But proposals to construct wind farms in real-world places elicit less support. Wind turbines in the Highlands and off the coast of Scotland have produced heated debate over the benefits of clean energy versus the costs of altering treasured scenic views.

Social traps challenge us to reconcile our right to pursue our personal well-being with our responsibility for the well-being of all. Psychologists have therefore explored ways to convince people to cooperate for their mutual betterment—through agreed-upon *regulations,* through better *communication,* and through promoting *awareness* of our responsibilities toward community, nation, and the

whole of humanity (Dawes, 1980; Kraft-Todd et al., 2015; Linder, 1982; Sato, 1987). Given effective regulations, communication, and awareness, people more often cooperate, whether playing a laboratory game or the real game of life.

Enemy Perceptions

Psychologists have noted that those in conflict have a curious tendency to form diabolical images of one another. These distorted images are, ironically, so similar that we call them **mirror-image perceptions:** As we see "them"—as untrustworthy, with evil intentions—so "they" see us. Each demonizes the other: "My political party, unlike the other party, has the nation's best interests at heart" (Waytz et al., 2014).

Mirror-image perceptions can often feed a vicious cycle of hostility. If Juan believes Maria is annoyed with him, he may snub her, causing her to act in ways that justify his perception. As with individuals, so with countries. Perceptions can become **self-fulfilling prophecies**—beliefs that confirm themselves by influencing the other country to react in ways that seem to justify those beliefs. In the real world, we make what we believe.

Individuals and nations alike tend to see their own actions as responses to provocation, not as the causes of what happens next. Perceiving themselves as returning tit for tat, they often hit back harder, as University College London volunteers did in one experiment (Shergill et al., 2003). Their task: After feeling pressure on

their own finger, they used a mechanical device to press on another volunteer's finger. Although told to reciprocate with the same amount of pressure, they typically responded with about 40 percent more force than they had just experienced. Despite seeking only to respond in kind, their touches soon escalated to hard presses, much as when each child involved in a fight asserts "I just touched them, but they hit me!" Mirror-image perceptions feed similar cycles of hostility on the world stage. To most people, torture seems more justified when done by "us" rather than "them" (Tarrant et al., 2012).

The point is not that truth must lie midway between two such views (one may be more accurate). The point is that enemy perceptions often form mirror images.

ANSWERS IN APPENDIX E

Promoting Peace

LOQ 44-6

What can we do to promote peace?

How can we make peace? Can contact, cooperation, communication, and conciliation transform the antagonisms fed by prejudice and conflicts into attitudes that promote peace? Research indicates that, in some cases, they can.

Contact

Does it help to put two conflicting parties into close contact? It depends. Negative contact increases disliking (Kotzur & Wagner, 2021). But positive contact—especially noncompetitive contact between parties of equal status, such as fellow store clerks—typically helps. Initially prejudiced co-workers of different races have, in such circumstances, usually come to accept one another. This finding is confirmed by studies of face-to-face contact between majority people and outgroups, such as ethnic minorities, older people, LGBTQ people, and people with disabilities. Among the quarter-million people studied across 38 nations, contact has correlated with (and in experiments has led to) more positive and empathic attitudes and reduced dehumanization (Bruneau et al., 2021; Pettigrew & Tropp, 2011; Tropp & Barlow, 2018). Some examples:

- Countries and U.S. states that have the most immigrants tend to be the most supportive of immigrants; outgroup prejudice is strongest in places with few immigrants (Myers, 2018; Shrira, 2020; Wagner et al., 2020).
- Straight, cisgender people's attitudes toward gay and transgender people are influenced not only by *what* they know but also by *whom* they know (Brown, 2017; DellaPosta, 2018). In surveys, the

reason people most often give for becoming more supportive of same-sex marriage is "having friends, family, or acquaintances who are gay or lesbian" (Pew, 2013). And in the United States, where 87 percent of people now say they know someone who is gay, attitudes toward same-sex marriage have become more accepting (McCarthy, 2019; Pew, 2016). Friendly contact—say, between Black and White students assigned to share a college dorm room—improves explicit and implicit attitudes toward others of the different race, and even toward other racial groups (Bruneau et al., 2021; Onyeador et al., 2020).

- More than 100 studies reveal that even "extended contact"—knowing that ingroup friends have outgroup friends—improves attitudes toward the outgroup (Zhou et al., 2019). Straight people often are more accepting of gay people if their straight friends have gay friends.

However, contact is not always enough. Despite laws that forbid school segregation, ethnic groups often resegregate themselves in lunchrooms, in classrooms, and elsewhere on school grounds (Alexander & Tredoux, 2010; Clack et al., 2005; Schofield, 1986). People in each group often think that they would welcome more contact with the other group, but they assume the other group does not reciprocate the wish (Richeson & Shelton, 2007). "I don't reach out to them because I don't want to be rebuffed; they don't reach out to me, because they're just not interested." When such mirror-image misperceptions are corrected, friendships may form and prejudices melt.

> **"Prejudice is learned behavior that can be unlearned."** — Desmond & Leah Tutu Legacy Foundation, 2019

Cooperation

To see if enemies could overcome their differences, researcher Muzafer Sherif (1966) set a conflict in motion. He randomly separated 22 Oklahoma City boys into two separate camp areas. Then he had the two groups compete for prizes in a series of activities. Before long, each group became intensely proud of itself and hostile to the other group's "sneaky," "smart-alecky stinkers." Food wars broke out. Cabins were ransacked. Fistfights had to be broken up by camp counselors. Brought together, the two groups avoided each other, except to taunt and threaten. Little did they know that within a few days, they would be friends.

> **"Me against my brother, my brothers and me against my cousins, then my cousins and me against strangers."** — Bedouin proverb

Sherif accomplished this by giving them **superordinate goals**—shared goals that could be achieved only through cooperation. When he arranged for the camp water supply to "fail," all 22 boys had to work together to restore the water. To rent a movie in those pre-streaming days, they all had to pool their resources. To move a stalled truck, everyone needed to combine their strength, pulling and pushing

together. Having used isolation and competition to make strangers into enemies, Sherif used shared predicaments and goals to turn enemies into friends. What reduced conflict was not mere contact, but *cooperative* contact. When diverse people team up as equals and collaborate toward a shared goal, animosities abate and friendships form.

Rosalind Beckton

Strangers coming together When a family got stuck in a Florida rip current, no less than 80 of their fellow beachgoers formed a human chain, rescuing them. One of the witnesses, Rosalind Beckton, wrote: “All races & ages join[ed] together to save lives” (AP, 2017).

Critics suggest that Sherif’s research team encouraged the conflict, hoping the study would illustrate their expectations about socially toxic competition and socially beneficial cooperation (Perry, 2018). Yet, shared predicaments or a common enemy do have powerfully unifying effects. Those facing rejection or discrimination have

developed strong ingroup identification (Bauer et al., 2014; Ramos et al., 2012). Youth exposed to war also typically bond with one another (Bauer et al., 2014). Israeli children growing up in conflict areas often develop conflict-supportive perceptions, beliefs, and emotions regarding their shared adversary (Nasie et al., 2016). Such interpretations build ingroup solidarity but also insensitivity to the pain experienced by those in the outgroup (Levy et al., 2016). In the aftermath of a divisive U.S. primary election, party members will usually reunify when facing their shared threat—the opposing party candidate. At such times, cooperation can lead people to define a new, inclusive group that dissolves their former subgroups (Dovidio & Gaertner, 1999). If serving as a peacemaker, you might seat members of two groups not on opposite sides, but alternately around a table. Give them a new, shared name. Have them work together. Enable them to see each other as part of one larger group. Then watch "us" and "them" become "we."

If cooperative contact between rival group members encourages positive attitudes, might this principle bring diverse students together? Could cooperative learning in classrooms create interracial friendships, while also enhancing student achievement? Experiments with adolescents from many countries confirm that the answer to both questions is *Yes* (Tropp et al., 2022). In the classroom as in the sports arena, members of multiethnic groups who work together on projects typically come to feel friendly toward one another. Knowing this, thousands of teachers have made multiethnic cooperative learning part of their classroom experience.

Rabie Zakaria

Superordinate goals override differences
Teaming up as equals and cooperating to achieve a shared goal is an optimal way to break down social barriers. When Iraqi Christians were assigned to play with Muslims on the same soccer team (as opposed to playing on all-Christian teams), they were later more likely to train with Muslims and register to play on a Christian-Muslim mixed soccer team (Mousa, 2020).

The power of cooperative activity to make friends of former enemies has led psychologists to urge increased international exchange and cooperation. Some experiments have found that just imagining the shared threat of global climate change reduces international hostilities (Pyszczynski et al., 2012). From adjacent Brazilian tribes to European countries, formerly conflicting groups have managed to build interconnections, interdependence, and a shared social identity as they seek common goals (Fry, 2012). As we engage in mutually beneficial trade, as we work to protect our common destiny on this fragile planet, and as we become more aware that our hopes and fears are shared, we can transform misperceptions that feed conflict into feelings of solidarity based on common interests.

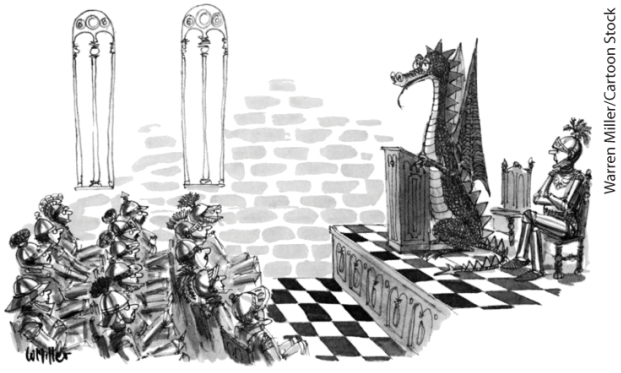
"Most of us have overlapping identities which unite us with very different groups. We *can* love what we are, without hating what—and who—we are *not*. We can thrive in our own tradition, even as we learn from others." — UN Secretary-General Kofi Annan, Nobel Peace Prize lecture, 2001

Communication

When real-life conflicts become intense, a third-party mediator—a marriage counselor, labor mediator, diplomat, community volunteer—may facilitate much-needed communication (Rubin et al., 1994). Mediators help each party voice its viewpoint and understand the other's needs and goals. If successful, mediators can replace a competitive *win-lose* orientation with a cooperative *win-win* orientation that leads to a mutually beneficial resolution. A classic example: Two friends, after quarreling over an orange, agreed to split it. One squeezed his half for juice. The other used the peel from her half to flavor a cake. If only the two had communicated their motives to one another, they could have hit on the win-win solution of one having all the juice, the other all the peel.

Byron Buck

Finding common ground In local communities across the United States, mediators are helping "red" (conservative) and "blue" (liberal) citizens discover their common ground and form friendships (see BraverAngels.org). My Country Talks is an international platform with similar goals. They set up "one-on-one discussions between people with completely different views" to encourage civil political dialogue (MyCountryTalks.org, 2021).



Conciliation

Understanding and cooperative resolution are most needed, yet least likely, in times of anger or crisis (Bodenhausen et al., 1994; Tetlock, 1988). When conflicts intensify, images become more stereotyped, judgments more rigid, and communication more difficult. Each party is likely to threaten, coerce, or retaliate. In the weeks before the 1990 Gulf War, U.S. President George H. W. Bush threatened, in the full glare of publicity, to "kick Saddam's ass." Iraqi president Saddam Hussein communicated in kind, threatening to make Americans "swim in their own blood."

Under such conditions, is there an alternative to war or surrender? Social psychologist Charles Osgood (1962, 1980) advocated a strategy of *Graduated and Reciprocated Initiatives in Tension-Reduction,* nicknamed **GRIT.** In applying GRIT, one side first announces its recognition of mutual interests and its intent to reduce tensions. It then initiates one or more small, conciliatory acts. Without weakening

one's retaliatory capability, this modest beginning opens the door for reciprocity by the other party. Should the enemy respond with hostility, one reciprocates in kind. But so, too, with any conciliatory response.

In laboratory experiments, small conciliatory gestures—a smile, a touch, a word of apology—have allowed both parties to begin edging down the tension ladder to a safer rung where communication and mutual understanding can begin (Lindskold, 1978; Lindskold & Han, 1988). In a real-world international conflict, U.S. President John F. Kennedy's gesture of stopping atmospheric nuclear tests began a series of reciprocated conciliatory acts that culminated in the 1963 atmospheric test-ban treaty between the United States and the Soviet Union.

Warren Miller/Cartoon Stock

"To begin with, I would like to express my sincere thanks and deep appreciation for the opportunity to meet with you. While there are still profound differences between us, I think the very fact of my presence here today is a major breakthrough."

As working toward shared goals reminds us, we are more alike than different. Civilization advances not by conflict and cultural isolation,

but by tapping the knowledge, the skills, and the arts that are each culture's legacy to the whole human race. Open societies are enriched by cultural sharing (Sowell, 1991). We have China to thank for paper and printing and for the magnetic compass that opened the great explorations. We have Egypt to thank for trigonometry. We have the Islamic world and India's Hindus to thank for our Arabic numerals. While celebrating and claiming these diverse cultural legacies, we can also welcome the continuing enrichment of today's cultural diversity. We can view ourselves as instruments in a human orchestra. And we can therefore each affirm our own culture's heritage while building bridges of communication, understanding, and cooperation across our cultural traditions.

"Peace is not just the absence of conflict; peace is the creation of an environment where all can flourish, regardless of race, color, creed, religion, gender, class, caste, or any other social markers of difference." — Former President of South Africa and anti-apartheid activist Nelson Mandela (2004).

Ask Yourself

Do you regret arguing with a friend or not getting along with a family member? How might you use these peace-promoting principles to resolve such conflicts, now or in the future?

Module 44: Prosocial Relations

Learning Objectives

Test Yourself Answer these repeated Learning Objective Questions on your own (before "showing" the answers here, or checking the answers in Appendix D) to improve your retention of the concepts (McDaniel et al., 2009, 2015).

LOQ 44-1: Why do we befriend or fall in love with some people but not others?

LOQ 44-2: How does romantic love typically change as time passes?

LOQ 44-3: What is *altruism?* When are people most—and least—likely to help?

LOQ 44-4: How do social exchange theory and social norms explain helping behavior?

LOQ 44-5: How do social traps and mirror-image perceptions fuel social conflict?

LOQ 44-6: What can we do to promote peace?

Terms and Concepts to Remember

Test Yourself Write down the definition in your own words, then check your answer.

mere exposure effect
passionate love
companionate love
equity
self-disclosure
altruism
diffusion of responsibility
bystander effect
social exchange theory
reciprocity norm
social-responsibility norm
conflict
social trap
mirror-image perceptions
self-fulfilling prophecy
superordinate goals
GRIT

Module Test

Test Yourself Answer the following questions on your own first, then "show" the answers here, or check your answers in Appendix E.

1. The more familiar a stimulus becomes, the more we tend to like it. This exemplifies the _____ _____ effect.

2. A happy couple celebrating their fiftieth wedding anniversary is likely to experience deep _____ love, even though their _____ love has probably decreased over the years.

3. After vigorous exercise, you meet an attractive person, and you are suddenly seized by romantic feelings for that person. This response supports the two-factor theory of emotion, which assumes that emotions, such as passionate love, consist of physical arousal plus
   a. a reward.
   b. proximity.
   c. companionate love.
   d. our interpretation of that arousal.

4. The bystander effect states that a particular bystander is less likely to give aid if
   a. the victim is similar to the bystander in appearance.
   b. no one else is present.
   c. other people are present.
   d. the incident occurs in a deserted or rural area.

5. Our enemies often have many of the same negative impressions of us as we have of them. This exemplifies the concept of _____-_____ perceptions.

6. One way of resolving conflicts and fostering cooperation is by giving rival groups shared goals that help them override their differences. These are called _____ goals.

CHAPTER 14
Personality (Modules 45–47)

MODULE 45 Introduction to Personality and Psychodynamic Theories

- What Is Personality?
- Psychodynamic Theories

MODULE 46 Humanistic Theories and Trait Theories

- Humanistic Theories

Trait Theories
THINKING CRITICALLY ABOUT: The Stigma of Introversion
MODULE 47 Social-Cognitive Theories and the Self
Social-Cognitive Theories
Exploring the Self

Lady Gaga dazzles millions with her unique musical arrangements, tantalizing outfits, and memorable performances. Her most predictable trait is her unpredictability. At an MTV Video Music Awards show, she stirred up debate by wearing a meat dress. A decade later, she performed the National Anthem at the most mainstream of events, the inauguration of U.S. President Joseph Biden.

Yet even unpredictable Lady Gaga exhibits distinctive and enduring ways of thinking, feeling, and behaving. Her fans and critics alike can depend on her openness to new experiences and the energy she gets from the spotlight. And they can also rely on her painstaking dedication to her performances. She describes her high school self as "very dedicated, very studious, and very disciplined." Now, in adulthood, she shows similar self-discipline: "I'm very detailed—every minute of the show has got to be perfect." Modules 45, 46, and 47 focus on our *personality*—our unique and persistent patterns of thinking, feeling, and behaving.

Much of this book deals with personality. Other modules consider biological influences on personality; personality development across the life span; how personality relates to learning, motivation, emotion, and health; social influences on personality; and disorders of personality.

These modules focus on personality itself—what it is and how researchers study it.

We begin with two important theories of personality that have become part of Western culture: *psychodynamic theories* and *humanistic theories* (Modules 45 and 46). These sweeping perspectives on human nature laid the foundation for later personality theories and for what Module 47 presents: newer scientific explorations of personality.

MODULE 45: Introduction to Personality and Psychodynamic Theories

Today's personality researchers study the basic dimensions of personality, and the interaction of persons and environments. They also study self-esteem, self-serving bias, and cultural influences on our concept of self—that sense of "Who I am." And they study the unconscious mind—with findings that probably would have surprised even Freud.

What Is Personality?

Learning Objective Question LOQ 45-1

What is *personality,* and what theories inform our understanding of personality?

Psychologists have varied ways to view and study **personality**—our characteristic pattern of thinking, feeling, and acting. Sigmund Freud's *psychoanalytic theory* proposed that childhood sexuality and unconscious motivations influence personality. The *humanistic theories* focused on our inner capacities for growth and self-fulfillment. Later theorists built upon these two broad perspectives. *Trait theories* examine characteristic patterns of behavior *(traits).*

Social-cognitive theories explore the interaction between people's traits (including their thinking) and their social context. Let's begin with Freud's work, and its modern-day descendant, *psychodynamic theories.*

Macmillan Learning

Sigmund Freud (1856–1939) "I was the only worker in a new field."

Psychodynamic Theories

Psychodynamic theories of personality view human behavior as a dynamic interaction between the conscious mind and unconscious mind, including associated motives and conflicts. These theories descended from Freud's **psychoanalysis**—his theory of personality and the associated treatment techniques. Freud was the first to focus clinical attention on our unconscious mind.

Freud's Psychoanalytic Perspective: Exploring the Unconscious

LOQ 45-2

How did Freud's treatment of psychological disorders lead to his view of the unconscious mind?

On the first day of class, when I [ND] ask students to name one psychologist, they always mention Freud. Although today's psychologists question many of his ideas, Freud remains psychology's best-known person (Diener et al., 2014). In the popular mind, he is to psychology what Louis Armstrong is to jazz music. Freud's influence lingers not only in psychiatry and clinical psychology, but also in literary and film interpretation. Almost 9 in 10 U.S. college courses that reference psychoanalysis have been outside of psychology departments (Cohen, 2007). Freud's early twentieth-century concepts penetrate our twenty-first-century language. Without realizing their source, we may speak of *ego, repression, projection, complex* (as in "inferiority complex"), *sibling rivalry, Freudian slips,* and *fixation.* So, who was Freud, and what did he teach?

Like all of us, Sigmund Freud was a product of his times. The late 1800s, the tail end of the Victorian era, was a time of tremendous discovery and scientific advancement, but also of sexual suppression and men's dominance. Gender roles were clearly defined, with men's superiority assumed. Only men's sexuality was generally

acknowledged (discreetly), whereas women's sexuality was dismissed or ignored. These assumptions influenced Freud's thinking about personality. He believed that psychological troubles resulted from men's and women's unresolved conflicts with their expected roles.

> **"The female … acknowledges the fact of her castration, and with it, too, the superiority of the male and her own inferiority; but she rebels against this unwelcome state of affairs."**
>
> — Sigmund Freud, *Female Sexuality,* 1931

Long before entering the University of Vienna in 1873, young Freud showed signs of independence and brilliance. He so loved reading plays, poetry, and philosophy that he once ran up a bookstore debt beyond his means. As a teen he often took his evening meal in his tiny bedroom in order to focus on his studies. After medical school he set up a private practice specializing in nervous disorders. Before long, however, he faced patients whose disorders made no neurological sense. A patient might have lost all feeling in a hand—yet there is no sensory nerve that, if damaged, would numb the entire hand and nothing else. Freud's search for a cause for such disorders set his mind running in a direction destined to change human self-understanding.

Do some neurological disorders have psychological causes? Observing patients led Freud to his "discovery" of the **unconscious.** He speculated that lost feeling in one's hand might be caused by a fear of touching one's genitals; that unexplained blindness or deafness might

be caused by not wanting to see or hear something that aroused intense anxiety. After some early unsuccessful trials with hypnosis, Freud turned to **free association**, in which he told the patient to relax and say whatever came to mind, no matter how embarrassing or trivial. He assumed that a line of mental dominoes had fallen from his patients' distant past to their troubled present. Free association, he believed, would allow him to retrace that line, following a chain of thought leading into the patient's unconscious. There, painful unconscious memories, often from childhood, could be retrieved, reviewed, and released.

Basic to Freud's theory was this belief that the mind is mostly hidden (**FIGURE 45.1**). Our *conscious* awareness is like the part of an iceberg that floats above the surface. Beneath this awareness is the larger *unconscious* mind, with its thoughts, wishes, feelings, and memories. We store some of these thoughts temporarily in a *preconscious* area, from which we can retrieve them into conscious awareness. Of greater interest to Freud was the mass of unacceptable passions and thoughts that he believed we *repress,* or forcibly block from our consciousness because they would be too unsettling to acknowledge. Freud believed that without our awareness, these troublesome feelings and ideas powerfully influence us, sometimes gaining expression in disguised forms—the work we choose, the beliefs we hold, our daily habits, our upsetting symptoms.

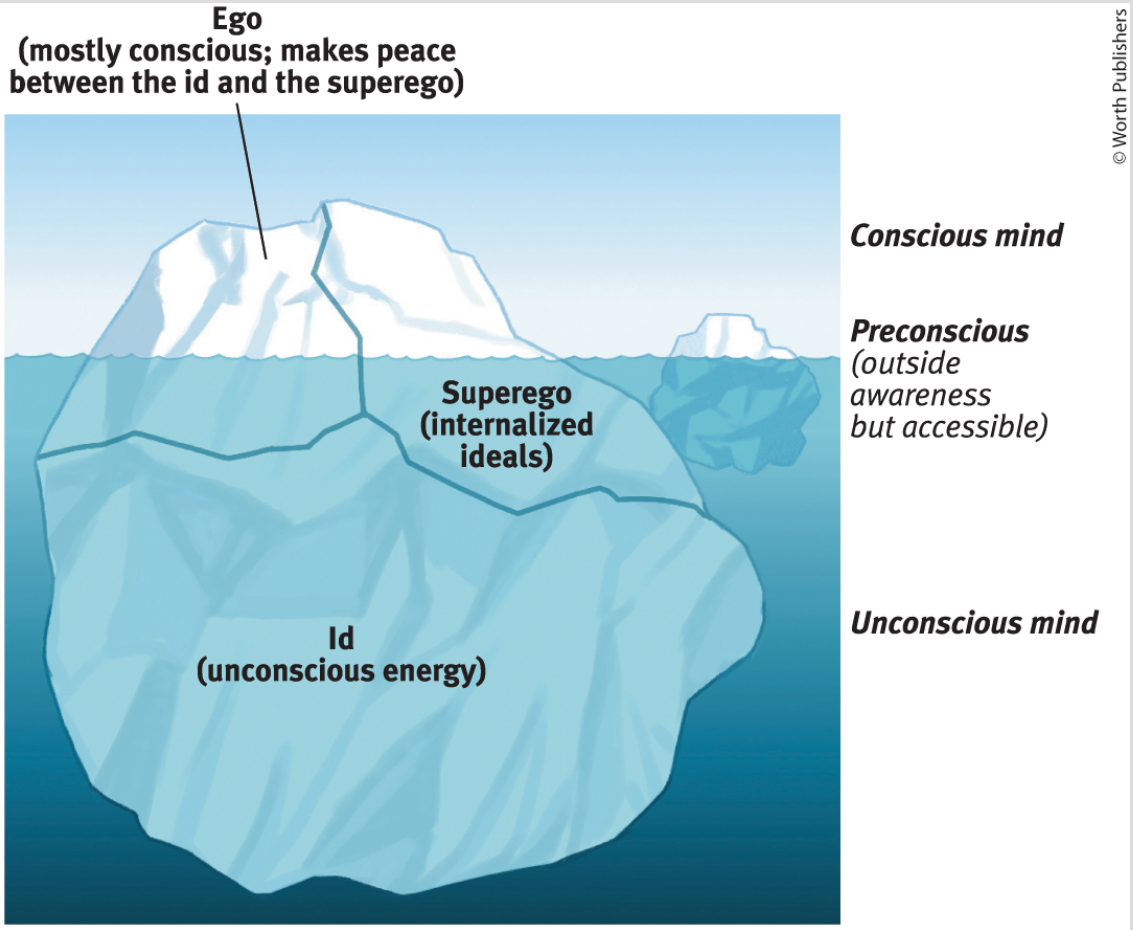

FIGURE 45.1 Freud's idea of the mind's structure Psychologists have used an iceberg image to illustrate Freud's idea that the mind is mostly hidden beneath the conscious surface.

Personality Structure

LOQ 45-3

What was Freud's view of personality?

Freud believed that human personality, including its emotions and strivings, arises from a conflict between impulse and restraint—between our aggressive, pleasure-seeking biological urges and our internalized social controls over these urges. Freud believed personality springs from our efforts to resolve this basic conflict—to express these impulses in ways that bring satisfaction without also bringing guilt or punishment. To understand the mind's dynamics during this conflict, Freud proposed three interacting systems: the *id, ego,* and *superego* (Figure 45.1).

The **id** stores unconscious energy, including our *libido*—a sexual energy force that fuels our pleasure-seeking. Freud argued that the id tries to satisfy our basic drives to survive, reproduce, and act aggressively. The id operates on the *pleasure principle:* It seeks immediate gratification. To understand the id's power, think of a newborn infant crying out for satisfaction, caring nothing for the outside world's conditions and demands. Or think of people who focus on the present more than the future—those who misuse tobacco, alcohol, or other drugs, and would sooner party now than sacrifice today's temporary pleasure for future success and happiness (Fernie et al., 2013; Friedel et al., 2014; Keough et al., 1999).

As the **ego** develops, a young child responds to the real world. The ego, operating on the *reality principle,* seeks to gratify the id's impulses in realistic ways to bring long-term pleasure. (Imagine what would happen if, lacking an ego, we acted on our unrestrained sexual or

aggressive impulses.) The ego contains our partly conscious perceptions, thoughts, judgments, and memories.

Around age 4 or 5, Freud theorized, a child's ego recognizes the demands of the newly emerging **superego**, the partly conscious voice of our moral compass (conscience) that forces the ego to consider not only the real but also the *ideal.* The superego focuses on how we *ought* to behave. It strives for perfection, judging actions and producing positive feelings of pride or negative feelings of guilt. Someone with an exceptionally strong superego may be virtuous yet guilt-ridden; another with a weak superego may be outrageously self-indulgent and remorseless.

Because the superego's demands often oppose the id's, the ego struggles to reconcile the two. The ego is the personality "executive," mediating among the impulsive demands of the id, the restraining demands of the superego, and the real-life demands of the external world. If virtuous Conner feels sexually attracted to Tatiana, he might make an ego-driven decision to satisfy both his id and superego by joining an organization where Tatiana volunteers regularly.

Personality Development

LOQ 45-4

What developmental stages did Freud propose?

Analysis of his patients' histories convinced Freud that personality forms during life's first few years. He concluded that children pass through a series of **psychosexual stages**, during which the id's pleasure-seeking energies focus on distinct pleasure-sensitive areas of the body called *erogenous zones* (TABLE 45.1). Each stage offers its own challenges, which Freud saw as conflicting tendencies.

TABLE 45.1 Freud's Psychosexual Stages

Stage	Focus
Oral (0–18 months)	Pleasure centers on the mouth—sucking, biting, chewing
Anal (18–36 months)	Pleasure focuses on bowel and bladder elimination; coping with demands for control
Phallic (3–6 years)	Pleasure zone is the genitals; coping with incestuous sexual feelings
Latency (6 years to puberty)	A phase of dormant sexual feelings
Genital (puberty on)	Maturation of sexual interests

Freud believed that during the *phallic stage,* for example, boys develop both unconscious sexual desires for their mother and jealousy and hatred for their father, whom they consider a rival. Such was Freud's (1897) own experience: "I have found, in my own case too, [the phenomenon of] being in love with my mother and jealous of my father, and I now consider it a universal event in early childhood." He believed these feelings cause boys to feel guilty and to fear punishment, perhaps by castration, from their father. He called this

collection of feelings the **Oedipus complex** after the Greek legend of Oedipus, whose failure to understand his unconscious desires led him to unknowingly kill his father and marry his mother. In Freud's era, some psychoanalysts believed that girls experience a parallel *Electra complex* (named after a mythological daughter who helped kill her mother to avenge her father's murder).

Children eventually cope with the threatening feelings, said Freud, by repressing them and by identifying with (trying to become like) the rival parent. It's as though something inside the child decides, "If you can't beat 'em [the same-sex parent], join 'em." Through this **identification** process, children's superegos gain strength as they incorporate many of their parents' values. Freud believed that identification with the same-sex parent provided what psychologists now understand more broadly as our *gender identity*—our sense of being male, female, neither, or some combination of male and female. Freud presumed that our early childhood relations—especially with our parents and other caregivers—influence our developing identity, personality, and frailties.

Sidney Harris/Cartoon Stock

"I heard that as soon as we become aware of our sexual impulses, whatever they are, we'll have to hide them."

In Freud's view, conflicts unresolved during earlier psychosexual stages could surface as maladaptive behavior in the adult years. At any point in the oral, anal, or phallic stages, strong conflict could lock, or **fixate**, the person's pleasure-seeking energies in that stage. A person who had been either orally overindulged or deprived (perhaps by abrupt, early weaning) might fixate at the oral stage. This orally fixated adult could exhibit either passive dependence (like that of a nursing infant) or an exaggerated denial of this dependence (by acting tough or uttering biting sarcasm). Or the person might continue to seek oral gratification by smoking or excessive eating. In such ways, Freud suggested, the twig of personality is bent at an early age.

Defense Mechanisms

LOQ 45-5

How did Freud think people defended themselves against anxiety?

Anxiety, said Freud, is the price we pay for civilization. As members of social groups, we must control our sexual and aggressive impulses, not act them out. But sometimes the ego fears losing control of this inner id-superego war. The presumed result is a dark cloud of unfocused anxiety that leaves us feeling unsettled but unsure why.

Freud proposed that the ego protects itself with **defense mechanisms**—tactics that reduce or redirect anxiety by distorting reality (**TABLE 45.2**). For Freud, *all defense mechanisms functioned indirectly and unconsciously.* Just as the body unconsciously defends itself against disease, the ego also unconsciously defends itself against anxiety. For example, **repression** banishes anxiety-arousing wishes and feelings from consciousness. According to Freud, *repression underlies all the other defense mechanisms.* However, because repression is often incomplete, repressed urges may appear as symbols in dreams or as slips of the tongue in conversation.

TABLE 45.2 Six Defense Mechanisms

Freud believed that *repression,* the basic mechanism that banishes anxiety-arousing impulses, enables other defense mechanisms, six of which are listed here.

Defense Mechanism	Unconscious Process Employed to Avoid Anxiety-Arousing Thoughts or Feelings	Example
Regression	Retreating to an earlier psychosexual stage, where some psychic energy remains fixated	A child reverts to the oral comfort of thumb sucking in the car on the way to their first day of school.
Reaction formation	Switching unacceptable impulses into their opposites	Repressing angry feelings, a person displays exaggerated friendliness.
Projection	Disguising one's own threatening impulses by attributing them to others	"The thief thinks everyone else is a thief" (an El Salvadoran saying).
Rationalization	Offering self-justifying explanations in place of the real, more threatening unconscious reasons for one's actions	A habitual drinker says they drink with their friends "just to be sociable."
Displacement	Shifting sexual or aggressive impulses toward a more acceptable or less threatening object or person	After being put in a time out, a child kicks the family dog.
Denial	Refusing to believe or even perceive painful realities	A partner denies evidence of their loved one's affair.

Regression

Freud believed he could glimpse the unconscious seeping through when a financially stressed patient, not wanting any large pills, said, "Please do not give me any bills, because I cannot swallow them." (Today we call these "Freudian slips.") Freud also viewed jokes as expressions of repressed sexual and aggressive tendencies, and dreams as the "royal road to the unconscious." The remembered content of dreams (their *manifest content*) he believed to be a censored expression of the dreamer's unconscious wishes (the dream's *latent content*). In his dream analyses, Freud searched for patients' inner conflicts.

"Good morning, beheaded—uh, I mean beloved."

"I remember your name perfectly but I just can't think of your face." — Oxford professor W. A. Spooner (1844–1930), famous for his linguistic flip-flops *(spoonerisms).* Spooner rebuked one student for "fighting a liar in the quadrangle" and another who "hissed my mystery lecture," adding, "You have tasted two worms."

Retrieval Practice

RP-1 According to Freud's ideas about the three-part personality structure, the _____ operates on the *reality principle* and tries to balance demands in a way that produces long-term pleasure rather than pain; the _____ operates on the *pleasure principle* and seeks immediate gratification; and the _____ represents the voice of our internalized ideals (our *conscience*).

RP-2 In the psychoanalytic view, conflicts unresolved during one of the psychosexual stages may lead to _____ at that stage.

RP-3 Freud believed that our defense mechanisms operate _____ (consciously/unconsciously) and defend us against _____.

ANSWERS IN APPENDIX E

The Neo-Freudian and Later Psychodynamic Theorists

LOQ 45-6

Which of Freud's ideas did his followers accept or reject?

In a historical period when people rarely talked about sex, and certainly not unconscious desires for sex with one's parent, Freud's writings sparked intense debate. "In the Middle Ages, they would have burned me," observed Freud to a friend. "Now they are content with burning my books" (Jones, 1957). Despite the controversy, Freud attracted followers. Several young, ambitious physicians formed an

inner circle around their strong-minded leader. These pioneering psychoanalysts, whom we often call *neo-Freudians,* adopted Freud's interviewing techniques and accepted his basic ideas: the personality structures of id, ego, and superego; the importance of the unconscious; the childhood roots of personality; and the dynamics of anxiety and the defense mechanisms. But they broke away from Freud in two important ways. First, they emphasized the conscious mind's role in interpreting experience and in coping with the environment. And second, they doubted that sex and aggression were all-consuming motivations. Instead, they tended to emphasize loftier motives and social interactions.

Alfred Adler and Karen Horney [HORN-eye], for example, agreed with Freud that childhood is important. But they believed that childhood *social,* not sexual, tensions are crucial for personality formation (Ferguson, 2003, 2020). Adler (who gave us the still popular *inferiority complex* idea) had struggled to overcome childhood illnesses and accidents. He believed that much of our behavior is driven by efforts to conquer childhood inferiority feelings that trigger our strivings for superiority and power. Horney said childhood anxiety triggers our desire for love and security. She also opposed Freud's assumptions that women have weak superegos and suffer "penis envy," and she attempted to balance his masculine bias.

Carl Jung [Yoong], Freud's disciple-turned-dissenter, placed less emphasis on social factors and agreed with Freud that the unconscious exerts a powerful influence. But to Jung, the unconscious

contains more than our repressed thoughts and feelings. He believed we also have a **collective unconscious**—shared memories and images that he called *archetypes*. Jung said that the collective unconscious explains why, for many people, spiritual concerns are deeply rooted and why people in different cultures share certain myths and images. Today's psychologists don't speak of a collective unconscious, but they do assume that our shared evolutionary history indeed shaped some universal dispositions, and that experience can leave *epigenetic* marks affecting gene expression.

Left to right: Macmillan Learning

Alfred Adler (1870–1937) "The individual feels at home in life and feels his existence to be worthwhile just so far as he is useful to others and is overcoming feelings of inferiority" (*Problems of Neurosis,* 1964).

Karen Horney (1885–1952) "The view that women are infantile and emotional creatures, and as such, incapable of responsibility and independence is the work of the masculine tendency to lower women's self-respect" (*Feminine Psychology,* 1932).

Carl Jung (1875–1961) "From the living fountain of instinct flows everything that is creative; hence the unconscious is the very source of the creative impulse" (*The Structure and Dynamics of the Psyche,* 1960).

Freud died in 1939. Since then, some of his ideas have been incorporated into the diverse perspectives that make up modern psychodynamic theory. "Most contemporary [psychodynamic]

theorists and therapists are not wedded to the idea that sex is the basis of personality," noted Drew Westen (1996). They "do not talk about ids and egos, and do not go around classifying their patients as oral, anal, or phallic characters." They assume, with Freud and with much support from today's psychological science, that much of our mental life is unconscious. With Freud, they also assume that we often struggle with inner conflicts among our wishes, fears, and values, and that childhood shapes our personality and ways of becoming attached to others.

Evaluating Freud's Psychoanalytic Perspective and Modern Views of the Unconscious

LOQ 45-7

How do contemporary psychologists view Freud's psychoanalysis?

Modern Research Contradicts Many of Freud's Ideas

We critique Freud from a twenty-first-century perspective. Freud did not have access to neurotransmitter or DNA studies, or to all that we have since learned about human development, thinking, and emotion. To criticize his theory by comparing it with today's thinking is like criticizing the Ford Model T by comparing it with a new Tesla

Model S. How tempting it is to judge the past from the perspective of our present.

> **"Many aspects of Freudian theory are indeed out of date, and they should be: Freud died in 1939, and he has been slow to undertake further revisions."** — Psychologist Drew Westen (1998)

Nevertheless, both Freud's devotees and his detractors agree that recent research contradicts many of his specific ideas. Today's developmental psychologists see our development as lifelong, not fixed in childhood. They doubt that infants' neural networks are mature enough to sustain as much emotional trauma as Freud assumed. Some think Freud overestimated parental influence and underestimated other factors, such as peer influence. These critics also doubt that conscience and gender identity form as the child resolves an Oedipus (or Electra) complex at age 5 or 6. We gain our gender identity earlier, and those who become strongly masculine or feminine do so even when they do not have a same-sex parent present. And they note that Freud's ideas about childhood sexuality arose from stories of childhood sexual abuse told by his female patients—stories that some scholars believe Freud doubted, and attributed to his patients' own childhood sexual wishes and conflicts (Esterson, 2001; Powell & Boer, 1994). Today, we know that *childhood sexual abuse happens,* and we also understand how Freud's questioning might have created false memories of abuse.

Modern dream research disputes Freud's belief that dreams disguise and fulfill wishes. And slips of the tongue can be explained as competition between similar verbal choices in our memory network. Someone who says, "I don't want to do that—it's a lot of brothel" may simply be blending *bother* and *trouble* (Foss & Hakes, 1978). Searching the more than 300,000 emails I [DM] have received since 2000, I see that friends have written me about their experience on "Wisconsin *Pubic* Radio" and about accessibility in "*pubic* venues." One analysis of 40,000 typing errors suggested that such mistakes are probably random typos (Stephens-Davidowitz, 2017).

History also has failed to support Freud's idea that suppressed sexuality causes psychological disorders. From Freud's time to ours, sexual inhibition has diminished; psychological disorders have not. Psychologists further criticize Freud's theory for its scientific shortcomings. It's important to remember that good scientific theories explain observations and offer testable hypotheses. Freud's theory rests on few objective observations, and parts of it offer few testable hypotheses. For Freud, his own recollections and interpretations of patients' free associations, dreams, and slips—sometimes selected to support his theory—were evidence enough.

What is the most serious problem with Freud's theory? It offers after-the-fact explanations of any characteristic (of one person's smoking, another's fear of horses, another's sexual orientation), yet fails to *predict* such behaviors and traits. If you feel angry at your mother's death, you illustrate Freud's theory because "your unresolved

childhood dependency needs are threatened." If you do not feel angry, you again illustrate his theory because "you are repressing your anger." That "is like betting on a horse after the race has been run" (Hall & Lindzey, 1978, p. 68). A good theory makes testable predictions.

So, should psychology post an "Allow Natural Death" order on this old theory? Freud's supporters object. To criticize Freudian theory for not making testable predictions is, they say, like criticizing baseball for not being an aerobic exercise—something it was never intended to be. Freud never claimed that psychoanalysis was predictive science. He merely claimed that, looking back, psychoanalysts could find meaning in our state of mind (Rieff, 1979).

Freud's supporters also note that some of his ideas *are* enduring. It was Freud who drew our attention to the unconscious and the irrational, at a time when such ideas were not popular. Many researchers have since studied our irrationality (Ariely, 2010; Thaler, 2015). Psychologist Daniel Kahneman (in 2002) and behavioral economist Richard Thaler (in 2017) each won Nobel Prizes for their studies of our faulty decision making. Freud also drew our attention to the importance of human sexuality, and to the tension between our biological impulses and our social well-being. It was Freud who challenged our self-righteousness, exposed our self-protective defenses, and reminded us of our potential for evil.

> **"Although [Freud] clearly made a number of mistakes in the formulation of his ideas, his understanding of unconscious mental processes was pretty much on target. In fact, it is very consistent with modern neuroscientists' belief that most mental processes are unconscious."** — Nobel Prize–winning neuroscientist Eric Kandel (2012)

Modern Research Challenges the Idea of Repression

Psychoanalytic theory hinges on the assumption that our mind often *represses* offending wishes, banishing them into the unconscious until they resurface, like a long-lost cat that finds its way home. Recover and resolve childhood's conflicted wishes, and emotional healing should follow. Repression became a widely accepted concept, used to explain hypnotic phenomena and psychological disorders. Some psychodynamic followers extended repression to explain apparently lost and recovered memories of childhood traumas (Boag, 2006; Cheit, 1998; Erdelyi, 2006). These psychodynamic beliefs have made their way into popular culture. In one survey, 88 percent of university students believed that painful experiences commonly get pushed out of awareness and into the unconscious (Garry et al., 1994).

Today's researchers agree that we sometimes preserve our self-esteem by neglecting threatening information (Green et al., 2008). Yet they also find that repression is rare, even in response to terrible trauma. Even those who have witnessed a parent's murder or survived Nazi

death camps have retained their unrepressed memories of the horror (Helmreich, 1992, 1994; Malmquist, 1986; Pennebaker, 1990).

Some researchers do believe that extreme, prolonged stress, such as the stress some severely abused children experience, might disrupt memory by damaging the hippocampus (Schacter, 1996). But the far more common reality is that high stress and associated stress hormones *enhance* memory. Indeed, rape, torture, and other traumatic events haunt survivors, who experience unwanted flashbacks. They are seared onto the soul. "You see the babies," said Holocaust survivor Sally H. (1979). "You see the screaming mothers. You see hanging people. You sit and you see that face there. It's something you don't forget."

> **"During the Holocaust, many children … were forced to endure the unendurable. For those who continue to suffer [the] pain is still present, many years later, as real as it was on the day it occurred."** — Eric Zillmer, Molly Harrower, Barry Ritzler, and Robert Archer, *The Quest for the Nazi Personality,* 1995

The Modern Unconscious Mind

LOQ 45-8

How has modern research developed our understanding of the unconscious?

Freud was right about a big idea that underlies today's psychodynamic thinking: We have limited access to all that goes on in our mind (Erdelyi, 1985, 1988; Norman, 2010). Our two-track mind has a vast unseen realm. Some researchers even argue that "most of a person's everyday life is determined by unconscious thought processes" (Bargh & Chartrand, 1999). (Perhaps, for example, you can recall being sad or angry without consciously knowing why.)

Many research psychologists now think of the unconscious not as seething passions and repressive censoring but as information processing that occurs without our awareness. To these researchers, the unconscious also involves

- the *schemas* that automatically control our perceptions and interpretations.
- the *priming* by stimuli to which we have not consciously attended.
- the right-hemisphere activity that enables the *split-brain* patient's left hand to carry out an instruction the patient cannot verbalize.
- the *implicit memories* of learned skills that operate without conscious recall, even in those with amnesia.
- the *emotions* that activate instantly, before conscious analysis.
- the *stereotypes* and *implicit prejudice* that automatically and unconsciously influence how we process information about others.

More than we realize, we fly on autopilot. Our lives are guided by off-screen, out-of-sight, unconscious information processing. The unconscious mind is vast. However, our current understanding of

unconscious information processing is more like the pre-Freudian view of an underground, unattended stream of thought from which spontaneous behavior and creative ideas surface (Bargh & Morsella, 2008).

Research also supports two of Freud's defense mechanisms. One study demonstrated *reaction formation* (trading unacceptable impulses for their opposite) in men who reported strong anti-gay attitudes. Compared with those who did not report such attitudes, these anti-gay men experienced greater physiological arousal (assessed with a device that measured blood flow to the penis) when watching videos of gay men having sex, even though they said the films did not make them sexually aroused (Adams et al., 1996). Likewise, some evidence suggests that people who have an unconscious same-sex sexual orientation—but who consciously identify as straight—report more negative attitudes toward gay men and lesbians (Weinstein et al., 2012).

Freud's *projection* (attributing our own threatening impulses to others) has also been confirmed. People do tend to see their traits, attitudes, and goals in others (Baumeister et al., 1998; Maner et al., 2005). Shown an ambiguous face, aggressive people often see anger (Brennan & Baskin-Sommers, 2020). Today's researchers call this the *false consensus effect*—the tendency to overestimate the extent to which others share our beliefs and behaviors. People who binge-drink or break speed limits tend to think many others do the same. Shortly before the 2020 U.S. presidential election, 83 percent of Democrats and 84 percent of

Republicans predicted that voters would elect *their* party's presidential candidate (ISR, 2020). As we are, so we see others.

Finally, research has supported Freud's idea that we unconsciously defend ourselves against anxiety. Researchers have proposed that one source of anxiety is "the terror resulting from our awareness of vulnerability and death" (Greenberg et al., 1997). Hundreds of experiments testing **terror-management theory** show that thinking about one's mortality—for example, by writing a short essay on dying and its associated emotions—provokes various terror-management defenses (Burke et al., 2010). For example, death anxiety increases aggression toward rivals and heightens esteem for oneself (Cohen & Solomon, 2011; Koole et al., 2006).

"It says, 'Someday you will die.'"

Faced with a threatening world, people act not only to enhance their self-esteem but also to adhere more strongly to worldviews that answer questions about life's meaning. The prospect of death promotes religious sentiments, and deep religious convictions enable

people to be less defensive—less likely to rise in defense of their worldview—when reminded of death (Jonas & Fischer, 2006; Norenzayan & Hansen, 2006). Moreover, when contemplating death, people prioritize their close relationships (Cox & Arndt, 2012; Mikulincer et al., 2003). The actual death of loved ones can provoke protective responses as well. For years, I [ND] have studied the way people respond to thoughts about death—but it took the shock of my own mother's unexpected death to motivate me to start running again, and to live a healthier lifestyle (Hayasaki, 2014; Kashdan et al., 2014). Facing death can inspire us to affirm life.

ANSWERS IN APPENDIX E

Assessing Unconscious Processes

LOQ 45-9

What are *projective tests,* how are they used, and what are some criticisms of them?

Personality tests reflect the basic ideas of particular personality theories. So, what might be the assessment tool of choice for someone working in the Freudian tradition? It would need to provide some sort of road into the unconscious—to unearth the residue of early childhood experiences, move beneath surface thoughts, and reveal hidden conflicts and impulses. Objective assessment tools, such as agree-disagree or true-false questionnaires, would be inadequate because they would merely tap the conscious surface.

Henry Murray (1933) demonstrated a possible basis for such a test at a party hosted by his 11-year-old daughter. Murray engaged the children in a frightening game called "Murder." When shown some photographs after the game, the children perceived the photos as more malicious than they had before the game. These children, it seemed to Murray, had *projected* their inner feelings into the pictures.

A few years later, Murray introduced the **Thematic Apperception Test (TAT)**—a **projective test** in which people view ambiguous pictures and then make up stories about them. Shown a daydreaming boy, those who imagine he is fantasizing about an achievement are presumed to be projecting their own goals. "As a rule," said Murray, "the subject

leaves the test happily unaware that he has presented the psychologist with what amounts to an X-ray of his inner self" (quoted by Talbot, 1999).

Numerous studies suggest that Murray was right: The TAT provides a valid and reliable map of people's implicit motives (Jenkins, 2017). For example, such storytelling has been used to assess *achievement* and *affiliation motivation* (Drescher & Schultheiss, 2016; Schultheiss et al., 2014).

Swiss psychiatrist Hermann Rorschach [ROAR-shock; 1884–1922] created the most widely used projective test. He based his famous **Rorschach inkblot test** (**FIGURE 45.2**) on a childhood game. Unlike the TAT's natural life images, Rorschach and his friends would drip ink on a paper, fold it, and then say what they saw in the resulting inkblot (Sdorow, 2005). Do you see predatory animals or weapons? A Rorschach interpreter might speculate that you have aggressive tendencies. But is this a reasonable assumption, considering that inkblots don't have any real-life meaning? The answer varies.

Spencer Grant/Science Source

FIGURE 45.2 The Rorschach test In this projective test, people tell what they see in a series of symmetrical inkblots.

Some clinicians cherish the Rorschach test, convinced that it projects a client's inner motives to the outside world. Others view the test as a source of suggestive leads, an icebreaker, or a revealing interview technique.

But critics insist the Rorschach is no emotional MRI. They argue that only a few of the many Rorschach-derived scores, such as those for cognitive impairment and thought disorder, have demonstrated reliability and validity (Mihura et al., 2013, 2015; Wood et al., 2015). And inkblot assessments have inaccurately diagnosed many healthy adults as pathological (Wood, 2003; Wood et al., 2006).

"The Rorschach [inkblot test] has the dubious distinction of being, simultaneously, the most cherished and the most reviled of all psychological assessment tools." — John Hunsley and J. Michael Bailey (1999)

Module Test

Test Yourself Answer the following questions on your own first, then "show" the answers here, or check your answers in Appendix E.

1. According to Freud's view of personality structure, the "executive" system, the _____, seeks to gratify the

impulses of the _____ in more acceptable ways.

a. id; ego
b. ego; superego
c. ego; id
d. id; superego

2. Freud proposed that the development of the "voice of our moral compass" is related to the _____, which internalizes ideals and provides standards for judgments.

3. According to the psychoanalytic view of development, we all pass through a series of psychosexual stages, including the oral, anal, and phallic stages. Conflicts unresolved at any of these stages may lead to

a. dormant sexual feelings.
b. fixation at that stage.
c. preconscious blocking of impulses.
d. a distorted gender identity.

4. Freud believed that defense mechanisms are unconscious attempts to distort or disguise reality, all in an effort to reduce our _____.

5. Freud believed that we may block painful or unacceptable thoughts, wishes, feelings, or memories from consciousness through an unconscious process called _____.

6. In general, neo-Freudians such as Adler and Horney accepted many of Freud's views but placed more emphasis

than he did on

a. development throughout the life span.
b. the collective unconscious.
c. the role of the id.
d. social interactions.

7. Modern-day psychodynamic theorists and therapists agree with Freud about

a. the existence of unconscious mental processes.
b. the Oedipus complex.
c. the predictive value of Freudian theory.
d. the superego's role as the executive part of personality.

8. Which of the following is NOT part of the contemporary view of the unconscious?

a. Repressed memories of anxiety-provoking events
b. Schemas that influence our perceptions and interpretations
c. Stereotypes that affect our information processing
d. Instantly activated emotions and implicit memories of learned skills

MODULE 46: Humanistic Theories and Trait Theories

By the 1960s, some personality psychologists had become discontented with the sometimes bleak focus on drives and conflicts in psychodynamic theory, and the mechanistic psychology of B. F. Skinner's *behaviorism*. Two pioneering theorists—Abraham Maslow and Carl Rogers—offered a *third-force perspective* that emphasized our potential for healthy personal growth.

Humanistic Theories

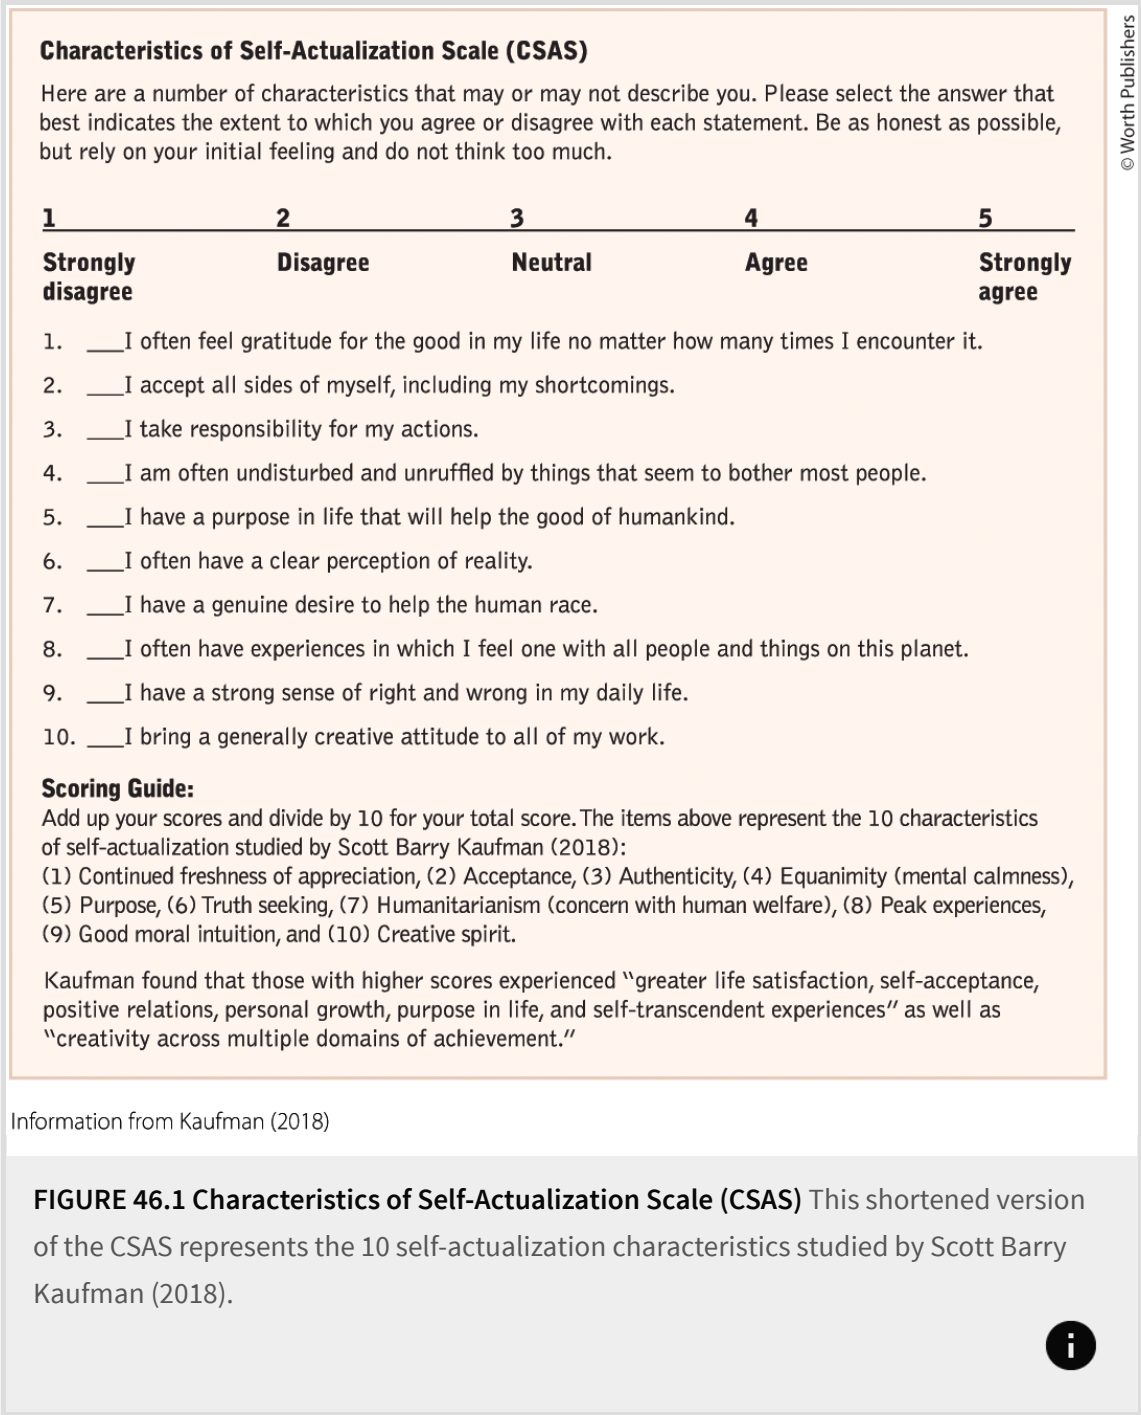
LOQ 46-1

How did humanistic psychologists view personality, and what was their goal in studying personality?

In contrast to Sigmund Freud's emphasis on disorders born out of dark conflicts, the **humanistic theorists** emphasized the ways people strive for self-determination and self-realization. In contrast to behaviorism's scientific objectivity, they studied people through self-reported experiences and feelings.

Abraham Maslow's Self-Actualizing Person

Maslow proposed that we are motivated by a **hierarchy of needs**. If our physiological needs are met, we become concerned with personal safety. If we achieve a sense of security, we then seek to love and to be loved. With our love needs satisfied, we seek self-esteem. Having achieved self-esteem, we ultimately seek **self-actualization** (the process of fulfilling our potential) and **self-transcendence** (meaning, purpose, and identity beyond the self).



Macmillan Learning

Abraham Maslow (1908–1970) "Any theory of motivation that is worthy of attention must deal with the highest capacities of the healthy and strong person as well as with the defensive maneuvers of crippled spirits" (*Motivation and Personality,* 1970, p. 33).

Maslow (1970) developed his ideas by studying healthy, creative people rather than clinical cases of troubled people. His description of self-actualization grew out of his study of people, such as Abraham

Lincoln, who seemed notable for their meaningful and productive lives. Maslow reported that such people shared certain characteristics: They were self-aware and self-accepting, open and spontaneous, loving and caring, and not paralyzed by others' opinions (Kaufman, 2018). Secure in their sense of who they were, their interests were task-centered rather than self-centered. Curious about the world, they embraced uncertainties and stretched themselves to seek out new experiences (Compton, 2018; Kashdan, 2009). Once they focused their energies on a particular task, they often regarded it as their life mission, or "calling" (Hall & Chandler, 2005). Most enjoyed a few deep relationships rather than many superficial ones. Many had been moved by spiritual or personal *peak experiences* that surpassed ordinary consciousness. These, said Maslow (1970), are mature adult qualities found in those who have learned enough about life to be compassionate, to have outgrown their mixed feelings toward their parents, to have found their calling, to have "acquired enough courage to be unpopular, to be unashamed about being openly virtuous." (Test your own level of self-actualization in **FIGURE 46.1**.)

Characteristics of Self-Actualization Scale (CSAS)

Here are a number of characteristics that may or may not describe you. Please select the answer that best indicates the extent to which you agree or disagree with each statement. Be as honest as possible, but rely on your initial feeling and do not think too much.

1	2	3	4	5
Strongly disagree	**Disagree**	**Neutral**	**Agree**	**Strongly agree**

1. ___I often feel gratitude for the good in my life no matter how many times I encounter it.
2. ___I accept all sides of myself, including my shortcomings.
3. ___I take responsibility for my actions.
4. ___I am often undisturbed and unruffled by things that seem to bother most people.
5. ___I have a purpose in life that will help the good of humankind.
6. ___I often have a clear perception of reality.
7. ___I have a genuine desire to help the human race.
8. ___I often have experiences in which I feel one with all people and things on this planet.
9. ___I have a strong sense of right and wrong in my daily life.
10. ___I bring a generally creative attitude to all of my work.

Scoring Guide:
Add up your scores and divide by 10 for your total score. The items above represent the 10 characteristics of self-actualization studied by Scott Barry Kaufman (2018):
(1) Continued freshness of appreciation, (2) Acceptance, (3) Authenticity, (4) Equanimity (mental calmness), (5) Purpose, (6) Truth seeking, (7) Humanitarianism (concern with human welfare), (8) Peak experiences, (9) Good moral intuition, and (10) Creative spirit.

Kaufman found that those with higher scores experienced "greater life satisfaction, self-acceptance, positive relations, personal growth, purpose in life, and self-transcendent experiences" as well as "creativity across multiple domains of achievement."

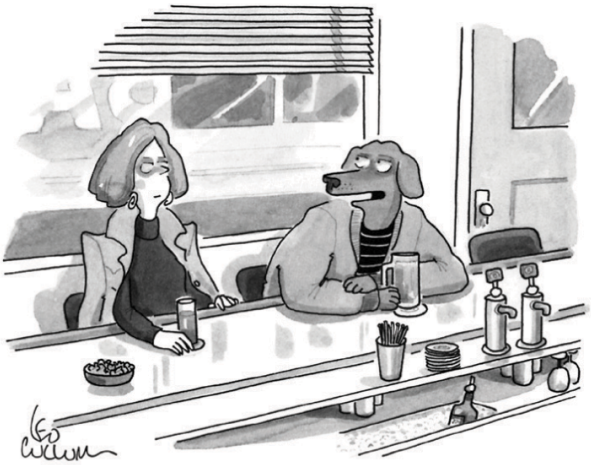
FIGURE 46.1 Characteristics of Self-Actualization Scale (CSAS) This shortened version of the CSAS represents the 10 self-actualization characteristics studied by Scott Barry Kaufman (2018).

Carl Rogers' Person-Centered Perspective

Fellow humanistic psychologist Carl Rogers agreed with much of Maslow's thinking. Rogers' *person-centered perspective* held that people

are basically good and are endowed with self-actualizing tendencies. Unless thwarted by an environment that inhibits growth, each of us is like an acorn, primed for growth and fulfillment. Rogers (1980) believed that a growth-promoting social climate provides

- ***acceptance.*** When people are *accepting,* they offer **unconditional positive regard,** an attitude of grace that values us even knowing our failings. It is a profound relief to drop our pretenses, confess our worst feelings, and discover that we are still accepted. In a good marriage, a close family, or an intimate friendship, we are free to be spontaneous without fearing the loss of others' esteem.



- ***genuineness.*** When people are *genuine,* they are open with their own feelings, drop their facades, and are transparent and self-disclosing.

- ***empathy.*** When people are *empathic,* they share and mirror others' feelings and reflect their meanings. "Rarely do we listen with real understanding, true empathy," said Rogers. "Yet listening, of this very special kind, is one of the most potent forces for change that I know."

Macmillan Learning

Carl Rogers (1902–1987) "The curious paradox is that when I accept myself just as I am, then I can change" (*On Becoming a Person,* 1961).

Leo Cullum/Cartoon Stock

"Yes, Doreen, I think I am capable of unconditional love."

Acceptance, genuineness, and empathy are, Rogers believed, the water, Sun, and nutrients that enable people to grow from acorns into vigorous oak trees. For "as persons are accepted and prized, they tend to develop a more caring attitude toward themselves" (Rogers, 1980, p.

116). When heard and accepted, people can listen to and accept their thoughts and feelings.

stefanamer/iStock/Getty Images

The picture of empathy Being open and sharing confidences is easier when the listener shows real understanding. Within such relationships we can relax and fully express our true selves.

The educator Alice Stewart Trillin discovered acceptance and genuineness at a camp for children with severe disorders. L., a "magical child," had genetic diseases that meant she had to be tube-fed and could walk only with difficulty. Trillin wondered "what this child's parents could have done … to make her the most optimistic, most enthusiastic, most hopeful human being I had ever encountered" (quoted in Trillin, 2006). One day Trillin spotted a note that L. received from her mom: "If God had given us all of the children in the world to choose from, L., we would only have chosen you." Inspired, Trillin approached a co-worker. "Quick. Read this," she whispered. "It's the secret of life."

Maslow and Rogers would have smiled knowingly. For them, a central feature of personality is one's **self-concept**—all the thoughts and feelings we have in response to the question, "Who am I?" If our self-concept is positive, we tend to act and perceive the world positively. If it is negative—if we fall far short of our *ideal self*—said Rogers, we feel dissatisfied and unhappy. A worthwhile goal for therapists, parents, teachers, and friends is therefore, he said, to help others know, accept, and be true to themselves.

Ask Yourself

Think back to a conversation you had when you knew someone was just waiting for their turn to speak instead of listening to you. Now consider the last time someone heard you with empathy. How did those two experiences differ?

Assessing the Self

LOQ 46-2

How did humanistic psychologists assess a person's sense of self?

Humanistic psychologists sometimes assessed personality by asking people to fill out questionnaires that would evaluate their self-concept. One questionnaire, inspired by Carl Rogers, asked people to describe themselves both as they would *ideally* like to be and as they *actually* are. When the ideal and the actual self are nearly alike, said

Rogers, the self-concept is positive. Assessing his clients' personal growth during therapy, he looked for successively closer ratings of actual and ideal selves.

Some humanistic psychologists believed that any standardized assessment of personality, even a questionnaire, is depersonalizing. Rather than forcing the person to respond to narrow categories, these humanistic psychologists presumed that interviews and intimate conversation would provide a better understanding of each person's unique experiences. Some researchers today believe our identity may be revealed using the *life story approach*—collecting a rich narrative detailing a person's unique life history (Adler et al., 2016; McAdams & Guo, 2015). A lifetime of stories can show more of a person's complete identity than can the responses to a few questions (Waters et al., 2019).

Evaluating Humanistic Theories

LOQ 46-3

How have humanistic theories influenced psychology? What criticisms have they faced?

One thing said of Freud can also be said of the humanistic psychologists: Their impact has been pervasive. Maslow's and Rogers' ideas have influenced counseling, education, child raising, and management. And they laid the groundwork for today's scientific *positive psychology* subfield.

These theorists have also influenced—sometimes in unintended ways—much of today's popular psychology. Is a positive self-concept the key to happiness and success? Do acceptance and empathy nurture positive feelings about ourselves? Are people basically good and capable of self-improvement? Many people answer *Yes, Yes,* and *Yes.* In 2006, U.S. high school students reported notably higher self-esteem and greater expectations of future career success than did students living in 1975, before humanistic psychology's feel-good philosophy infused U.S. culture (Twenge & Campbell, 2008). Given a choice, North American college students have said they'd rather get a self-esteem boost, such as a compliment or good grade on a paper, than enjoy a favorite food or sexual activity (Bushman et al., 2011). Humanistic psychology's message has been heard.

But the prominence of the humanistic perspective set off a backlash of criticism. First, said the critics, its concepts are vague and subjective. Consider Maslow's description of self-actualizing people as open, spontaneous, loving, self-accepting, and productive. Is this a scientific description? Or is it merely a description of the theorist's own values and ideals? Maslow, noted M. Brewster Smith (1978), offered impressions of his own personal heroes, such as Abraham Lincoln and Albert Einstein. Imagine another theorist who began with a different set of heroes—perhaps French military conqueror Napoleon and former U.S. President Donald Trump. This theorist might describe self-actualizing people as "undeterred by others' opinions," "motivated to achieve," and "comfortable with power."

Critics also objected to the idea that, as Rogers (1985) put it, "The only question which matters is, 'Am I living in a way which is deeply satisfying to me, and which truly expresses me?'" (quoted in Wallach & Wallach, 1985). This emphasis on *individualism*—trusting and acting on one's feelings, being true to oneself, fulfilling oneself—could lead to self-indulgence, selfishness, and an erosion of moral restraint (Campbell & Specht, 1985; Wallach & Wallach, 1983). Imagine working on a group project with people who refuse to complete any task that is not deeply satisfying or does not truly express their identity.

Humanistic psychologists have replied that a secure, nondefensive self-acceptance is actually the first step toward loving others. Indeed, people who feel intrinsically liked and accepted—for who they are, not just for their achievements—exhibit less defensive attitudes (Schimel et al., 2001). Those feeling liked and accepted by a romantic partner report being happier in their relationships and acting more kindly toward their partner (Gordon & Chen, 2010).

A final criticism leveled against humanistic psychology is that it is naive—that it fails to appreciate the reality of our human capacity for evil (May, 1982). Psychological science reminds us of this unfortunate capacity. Some situations can prompt us to believe lies or act cruelly (see the Social Psychology modules). *Deindividuation, groupthink,* and *group polarization* may accentuate our worst tendencies. And mere dislike can become prejudiced hatred. But as the humanistic psychologists remind us, there is another mountain of research that

testifies to our potential for goodness—for growth and gratitude, for humility and hope, for empathy and compassion.

Faced with a climate crisis, economic woes, and systemic racism, we may become apathetic from either of two rationalizations. One is a starry-eyed optimism that denies the threat ("People are basically good; everything will work out"). The other is a dark despair ("It's hopeless; why try?"). Action requires enough realism to fuel concern and enough optimism to provide hope. (Pessimism often fulfills its own predictions, by restraining our efforts at change.) Humanistic psychology, say the critics, encourages the needed hope but not the equally necessary realism about threats.

Igor Bobic/Huffington Post

Are we humans born to be bad or good? The lessons of psychological science mirror our cultural experience, where forces of good and bad sometimes collide, as Capitol Police Officer Eugene Goodman's bravery and quick-thinking protected lawmakers and staff from an invading mob that breached the U.S. Capitol in 2021.

ANSWERS IN APPENDIX E

Trait Theories

LOQ 46-4

How do psychologists use traits to describe personality?

Rather than focusing on unconscious forces and thwarted growth opportunities, some researchers attempt to define personality in terms of stable and enduring behavior patterns, such as Lady Gaga's self-discipline and openness to new experiences. This perspective can be traced in part to a remarkable meeting in 1919, when Gordon Allport, a curious 22-year-old psychology student, interviewed Sigmund Freud in Vienna. Allport soon discovered just how preoccupied the founder of psychoanalysis was with finding hidden motives, even in Allport's own behavior during the interview. That experience ultimately led Allport to do what Freud did not do: to describe personality in terms of fundamental **traits**, or people's characteristic behaviors and conscious motives (such as the curiosity

that actually motivated Allport to see Freud). Meeting Freud, said Allport, "taught me that [psychoanalysis], for all its merits, may plunge too deep, and that psychologists would do well to give full recognition to manifest motives before probing the unconscious." Allport came to define personality in terms of identifiable behavior patterns. He was concerned less with *explaining* individual traits than with *describing* them.

Like Allport, Isabel Briggs Myers (1987) and her mother, Katharine Briggs, wanted to describe important personality differences. They attempted to sort people according to Carl Jung's *personality types,* based on their responses to 126 questions. The *Myers-Briggs Type Indicator (MBTI),* available in 20+ languages, has been taken by millions of people, mostly for counseling, leadership training, and work-team development (CPP, 2017). It offers choices, such as "Do you usually value sentiment more than logic, or value logic more than sentiment?" Then it counts the test-taker's preferences, labels them as indicating, say, a "feeling type" or "thinking type," and feeds them back to the person in complimentary terms. Feeling types, for example, are told they are "sympathetic, appreciative, and tactful"; thinking types are told they are "good at analyzing." (Every type has its strengths, so everyone is affirmed.)

Most people agree with their announced MBTI profile, which mirrors their declared preferences. They may also accept their label as a basis for being matched with work or dating partners, and with tasks that supposedly suit their temperaments. But a National Research Council

report noted that despite the test's popularity in business and career counseling, its use has outrun research on its validity as a job performance predictor: "The popularity of this instrument in the absence of proven scientific worth is troublesome" (Druckman & Bjork, 1991, p. 101; see also Pittenger, 1993). Although research on the MBTI has been accumulating since those cautionary words were expressed, the test remains mostly a counseling and coaching tool, not a research instrument. Fortunately, newer research offers reliable and valid tools to explore traits.

Exploring Traits

We are each a unique complex of multiple traits. So how can we describe our personalities in a way that captures our individuality? We might describe an apple by placing it along several trait dimensions—relatively large or small, red or green, sweet or tart. By placing people on several trait dimensions simultaneously, psychologists can describe countless individual personality variations.

What trait dimensions describe personality? If you were looking at profiles on a dating app, what personality traits would give you the most useful information about each person? Allport and his associate H. S. Odbert (1936) counted all the words in an unabridged dictionary that could be used to describe people. There were almost 18,000! How, then, could psychologists condense the list to a manageable number of basic traits?

James Stevenson/Cartoon Stock

"Hello. This is Dial-a-Grump. What the hell do you want?"

Factor Analysis

One technique is *factor analysis,* a statistical procedure that identifies clusters (factors) of test items that tap basic components of a trait (McCabe & Fleeson, 2016). Imagine that people who describe themselves as outgoing also tend to say that they like excitement and practical jokes and dislike quiet reading. Such a statistically correlated cluster of behaviors reflects a basic factor, or trait—in this case, *extraversion.*

British psychologists Hans Eysenck and Sybil Eysenck [EYE-zink] believed that we can reduce many of our individual variations to two

dimensions: *extraversion–introversion* and *emotional stability–instability* (FIGURE 46.2).[1] People in 35 countries worldwide took the *Eysenck Personality Questionnaire*. When their answers were analyzed, the extraversion and emotionality (later called *neuroticism*) factors inevitably emerged as basic personality dimensions (Eysenck, 1990, 1992). The Eysencks believed, and research confirms, that these factors are genetically influenced.

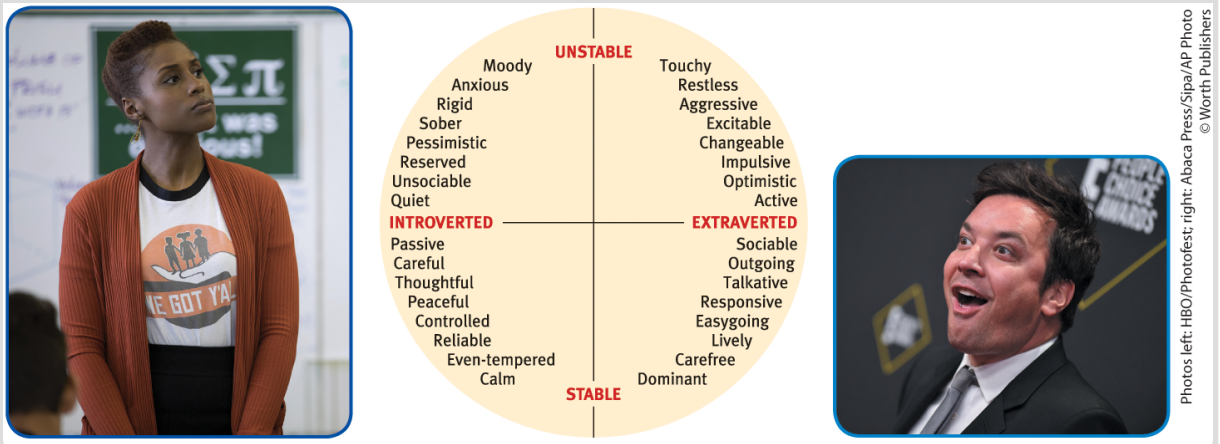

FIGURE 46.2 Two personality dimensions Mapmakers can tell us a lot by using two axes (north–south and east–west). Two primary personality factors (extraversion–introversion and stability–instability) are similarly useful as axes for describing personality variation. Varying combinations define other, more specific traits (Eysenck & Eysenck, 1963). Although many actors are extraverted, some, such as Issa Rae, are introverts—particularly capable of solitary study to become each character they portray. Professional comedians, such as Jimmy Fallon, are often natural extraverts (Irwing et al., 2020).

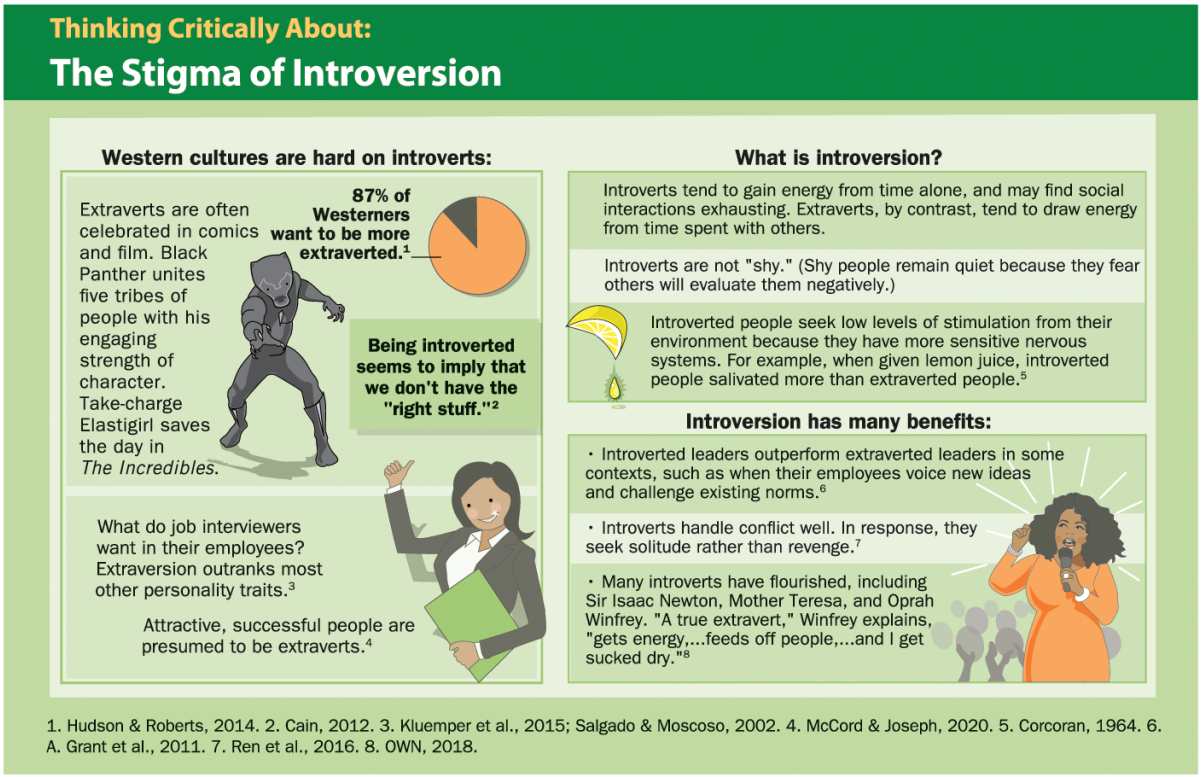
Biology and Personality



Brain-activity scans of extraverts add to the growing list of traits and mental states now being explored. Such studies indicate that

extraverts seek stimulation because their normal brain arousal is relatively low. For example, PET scans have shown that a frontal lobe area involved in behavior inhibition is less active in extraverts than in introverts (Johnson et al., 1999).

Our biology influences our personality. As we know from twin and adoption studies, compared with fraternal twins, identical twin personalities are much more similar (Loehlin & Martin, 2018; Mõttus et al., 2019). What's true of so much of human nature is also true of personality and life outcomes, which are influenced by many genes having small effects (Smith-Wooley et al., 2019; van den Berg et al., 2016). Our genes also influence the *temperament* and behavioral style that shape our personality. Jerome Kagan (2010), for example, has attributed differences in children's shyness and inhibition to their autonomic nervous system reactivity. Those with a reactive autonomic nervous system respond to stress with greater anxiety and inhibition. The fearless, curious child may become the extreme skier or mountain biker with a GoPro. (See Thinking Critically About: The Stigma of Introversion.)

LOQ 46-5

What are some common misunderstandings about introversion?

© Worth Publishers

Personality differences among dogs (in energy, affection, reactivity, and curious intelligence) are as evident, and as consistently judged, as personality differences among humans (Gosling et al., 2003; Jones & Gosling, 2005). Monkeys, bonobos, chimpanzees, orangutans, dolphins, orcas, sea lions, and even birds and fish also have distinct and stable personalities (Altschul et al., 2018; Morton et al., 2021; Úbeda et al., 2018; Weiss et al., 2017). Even conscientiousness varies among individual animals, from chimps to bees (Delgado & Sulloway, 2017). Through selective breeding, researchers can produce bold or shy birds. Both personality types have their place in natural history: In lean years, bold birds are more likely to find food; in abundant years, shy birds feed with less risk.

Macmillan Learning

Octopus personality The real-life Otto the octopus seems to love getting attention from visitors. But when his German aquarium closes during the winter, Otto acts like a bored prankster. He has juggled hermit crabs, squirted water at staff members, and broken his light by spraying it with water.

RP-3 Which two primary dimensions did Hans Eysenck and Sybil Eysenck propose for describing personality variation?

ANSWERS IN APPENDIX E

Assessing Traits

LOQ 46-6

What are *personality inventories,* and what are their strengths and weaknesses as trait-assessment tools?

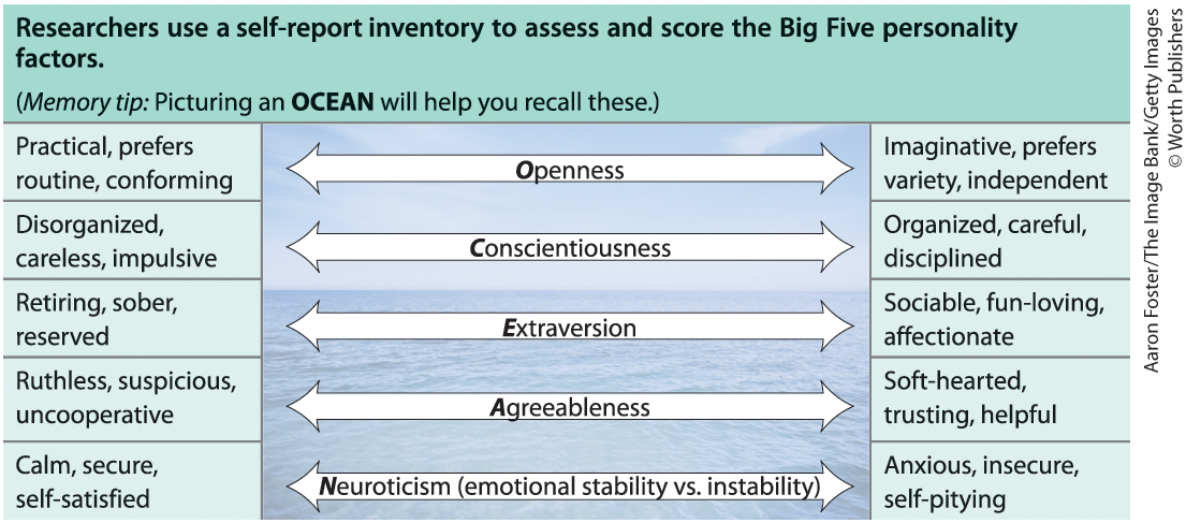
If stable and enduring traits guide our actions, can we devise valid and reliable tests of them? Several trait-assessment techniques exist—some more valid than others. Some provide quick assessments of a single trait, such as extraversion, anxiety, or self-esteem. **Personality inventories**—longer **self-report** questionnaires covering a wide range of feelings and behaviors—assess several traits at once.

The classic personality inventory is the **Minnesota Multiphasic Personality Inventory (MMPI).** Although the MMPI was originally developed to identify emotional disorders (still considered its most appropriate use), it also assesses people's personality traits. One of its creators, Starke Hathaway (1960), compared his effort with that of Alfred Binet. Binet, the founder of modern intelligence testing,

developed the first intelligence test by selecting items that identified children who would likely struggle to progress in French schools. Like Binet's items, the MMPI items were **empirically derived**: From a large pool of items, Hathaway and his colleagues selected those on which particular diagnostic groups differed. "My hands and feet are usually warm enough" may seem superficial, but it just so happened that anxious people were more likely to answer *False*. The researchers grouped the questions into 10 clinical scales, including scales that assess depressive tendencies, masculinity–femininity, and introversion–extraversion. Today's MMPI-2 has additional scales that assess work attitudes, family problems, and anger.

Whereas most projective tests (such as the Rorschach) are scored subjectively, personality inventories are scored objectively. Objectivity does not, however, guarantee validity. For example, individuals taking the MMPI for employment purposes can give socially desirable answers to create a good impression. But in so doing they may also score high on a *lie scale* that assesses faking (as when people respond *False* to a universally true statement such as "I get angry sometimes"). In other cases, the MMPI can be used to identify people pretending to have a disorder in order to avoid their responsibilities (Chmielewski et al., 2017). The MMPI's objectivity has contributed to its popularity and its translation into more than 100 languages.

> People have had fun spoofing the MMPI with their own mock items: "Weeping brings tears to my eyes," "Frantic screams make me nervous," and "I stay in the bathtub until I look like a raisin" (Frankel et al., 1983).



The Big Five Factors

LOQ 46-7

Which traits seem to provide the most useful information about personality variation?

Today's trait researchers believe that simple trait factors, such as the Eysencks' introversion–extraversion and stability–instability dimensions, are important, but they do not tell the whole story. A slightly expanded set of factors—dubbed the **Big Five factors** (also called the *five-factor model*)—does a better job (Costa & McCrae, 2011; Soto & John, 2017). If a test specifies where you are on the five dimensions (*openness, conscientiousness, extraversion, agreeableness,* and *neuroticism;* see **TABLE 46.1**), it has said much of what there is to say about your personality. The Big Five factors can also be used to understand both psychological flourishing and dysfunction (Bleidorn et al., 2020; Oltmanns et al., 2018; Wimmelmann et al., 2020).

TABLE 46.1 The "Big Five" Personality Factors

Information from McCrae & Costa (1986, 2008).

Around the world—across 56 nations and 29 languages in one study (Schmitt et al., 2007)—people describe others in terms roughly consistent with this list. The Big Five—today's "common currency for personality psychology" (Funder, 2001)—has been the most active personality research topic since the early 1990s and is currently our best approximation of the basic trait dimensions.

Big Five research has explored various questions:

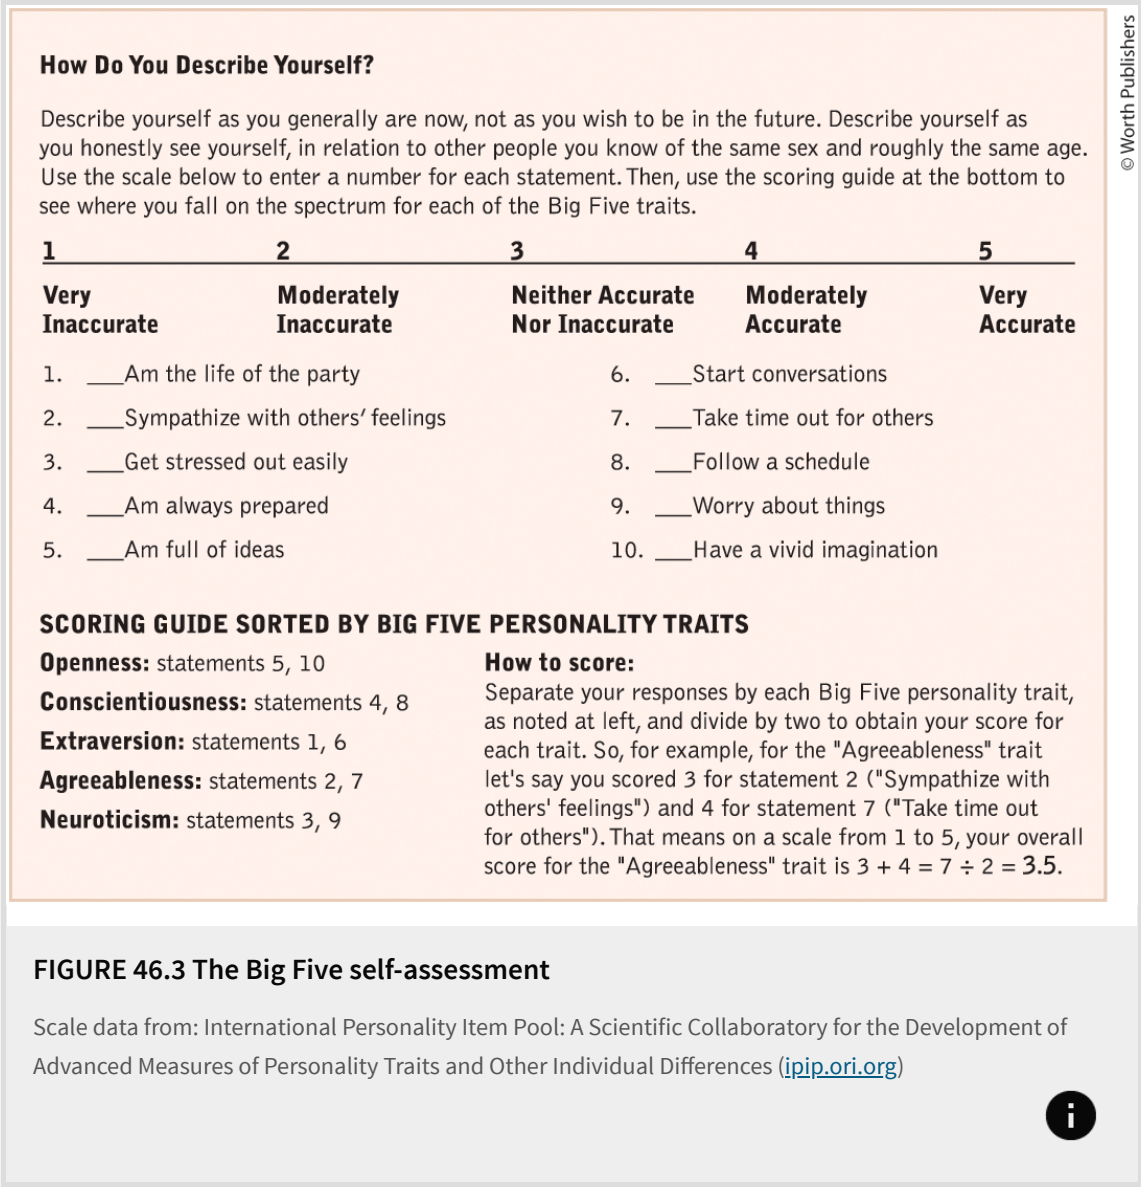
- ***How stable are these traits?*** Research teams have analyzed the traits of Americans, Australians, Icelanders, and Germans in adolescence and again 20 to 30 years later (Damian et al., 2019; Hoff et al., 2020; Wagner et al., 2019). The participants' personalities remained generally stable, but most people

exhibited a *maturity principle:* From adolescence onward, they became more conscientious and agreeable, and less neurotic (emotionally unstable) (Allemand et al., 2019; Atherton et al., 2021). People in Japan, who more often adapt their personality to their social environment, show somewhat more Big Five trait variation (Haas & vanDellen, 2020).

- ***Do self-ratings on these traits match others' ratings?*** The ratings of family and friends of our Big Five trait levels do resemble the ratings we give ourselves (Finnigan & Vazire, 2018; Luan et al., 2019).

- ***Do these traits reflect differing brain structure?*** The size and thickness of brain tissue correlates with several Big Five traits (DeYoung & Allen, 2019; Li et al., 2017; Riccelli et al., 2017). For example, those who score high on conscientiousness tend to have a larger frontal lobe area that aids in planning and controlling behavior. Brain connections also influence the Big Five traits (Toschi et al., 2018). People high in neuroticism have brains that are wired to experience stress intensely (Shackman et al., 2016; Xu & Potenza, 2012).

- ***Do these traits reflect birth order?*** After controlling for other variables such as family size, are first-born children, for example, more conscientious and agreeable? Contrary to popular opinion, several massive studies failed to find any association between birth order and personality (Damian & Roberts, 2015; Harris, 2009; Rohrer et al., 2015).



- ***How well do these traits apply to various cultures?*** The Big Five dimensions describe personality in various cultures reasonably well (H. Kim et al., 2018; Minkov et al., 2019; Schmitt et al., 2007). From herders in Kenya and Tanzania to gardeners in Mali, these traits help us understand basic features of personality (Thalmayer et al., 2020). After studying people from 50 cultures, Robert McCrae and 79 co-researchers concluded that Big Five traits "are common to all human groups" (2005).

- ***Do the Big Five traits predict our everyday behaviors?*** *Yes,* Big Five traits reliably predict important life outcomes (Soto, 2021). Conscientiousness predicts better school performance and workplace success (Mammadov, 2022; Nickel et al., 2019). (Maybe nice people finish first?) Agreeable people are caring and law-abiding, and were more likely to follow mobility restrictions to minimize Covid-19 spread (Chan et al., 2021; Zajenkowski et al., 2020). Extraverts post more on social media, more often become leaders, and spend less time at home (true even during the Covid pandemic) (Bowden-Green, 2020; Götz et al., 2021; Matz & Harari, 2021; Scott & Medeiros, 2020). People high in neuroticism were more stressed during the pandemic (Kroenke et al., 2020).

How do you shop and vote? Let me count the likes Researchers can use Facebook likes to predict individuals' Big Five traits, opinions, and political attitudes (Youyou et al., 2015). Companies sell "big data" for advertisers (who then personalize the ads you see) and to political campaigns, which can then target certain users with persuasive messages (Matz et al., 2017).

By exploring such questions, Big Five research has sustained trait psychology and has renewed appreciation for the importance of personality. (To describe your personality, try the brief self-assessment in **FIGURE 46.3**.) Traits matter.

How Do You Describe Yourself?

Describe yourself as you generally are now, not as you wish to be in the future. Describe yourself as you honestly see yourself, in relation to other people you know of the same sex and roughly the same age. Use the scale below to enter a number for each statement. Then, use the scoring guide at the bottom to see where you fall on the spectrum for each of the Big Five traits.

1	2	3	4	5
Very Inaccurate	**Moderately Inaccurate**	**Neither Accurate Nor Inaccurate**	**Moderately Accurate**	**Very Accurate**

1. ___Am the life of the party
2. ___Sympathize with others' feelings
3. ___Get stressed out easily
4. ___Am always prepared
5. ___Am full of ideas
6. ___Start conversations
7. ___Take time out for others
8. ___Follow a schedule
9. ___Worry about things
10. ___Have a vivid imagination

SCORING GUIDE SORTED BY BIG FIVE PERSONALITY TRAITS

Openness: statements 5, 10
Conscientiousness: statements 4, 8
Extraversion: statements 1, 6
Agreeableness: statements 2, 7
Neuroticism: statements 3, 9

How to score:
Separate your responses by each Big Five personality trait, as noted at left, and divide by two to obtain your score for each trait. So, for example, for the "Agreeableness" trait let's say you scored 3 for statement 2 ("Sympathize with others' feelings") and 4 for statement 7 ("Take time out for others"). That means on a scale from 1 to 5, your overall score for the "Agreeableness" trait is 3 + 4 = 7 ÷ 2 = 3.5.

RP-4 What are the *Big Five* personality factors, and why are they scientifically useful?

ANSWERS IN APPENDIX E

Evaluating Trait Theories

LOQ 46-8

Does research support the consistency of personality traits over time and across situations?

Are our personality traits stable and enduring? Or does our behavior depend on where and with whom we find ourselves? Cheerful, friendly children do tend to become cheerful, friendly adults. At a college reunion, I [DM] was amazed to find that my jovial former classmates were still jovial, the shy ones still shy, the happy-seeming people still smiling and laughing *50 years later.* But it's also true that a fun-loving jokester can suddenly turn serious and respectful at a job interview. New situations and major life events can shift the personality traits we express. Transitioning from high school to university or the workforce, we often become more agreeable, conscientious, and open-minded, and less neurotic (Bleidorn et al., 2018). Losing our job may make us less agreeable and open-minded (Boyce et al., 2015). But when we retire—losing our job *by choice*—we

often become more agreeable and open-minded (Schwaba & Bleidorn, 2019).

> **"There is as much difference between us and ourselves, as between us and others."** — Michel de Montaigne, *Essays,* 1588

The Person-Situation Controversy

Our behavior is influenced by the interaction of our inner disposition with our environment. Still, the question lingers: Which is more important? When we explore this *person-situation controversy,* we look for genuine personality traits that persist over time and across situations. Are some people dependably conscientious and others unreliable, some cheerful and others dour, some outgoing and others quiet? If we are to consider friendliness a trait, friendly people must act friendly at different times and places. Do they?

Longitudinal research follows lives through time. Some scholars (especially those who study infants) are impressed with personality change; others are struck by personality stability during adulthood. As **FIGURE 46.4** illustrates, data from 152 longitudinal studies reveal that personality trait scores are positively correlated with scores obtained an average of 7 years later, and that as people grow older, their personality stabilizes. Interests may change—the avid tropical-fish collector may become an avid gardener. Careers may change—the determined salesperson may become a determined social worker.

Relationships may change—the hostile son may become a hostile husband. But most people come to recognize and accept who they are. As researchers Robert McCrae and Paul Costa (1994) observed, our recognizing the inevitability of our personality is "the culminating wisdom of a lifetime."

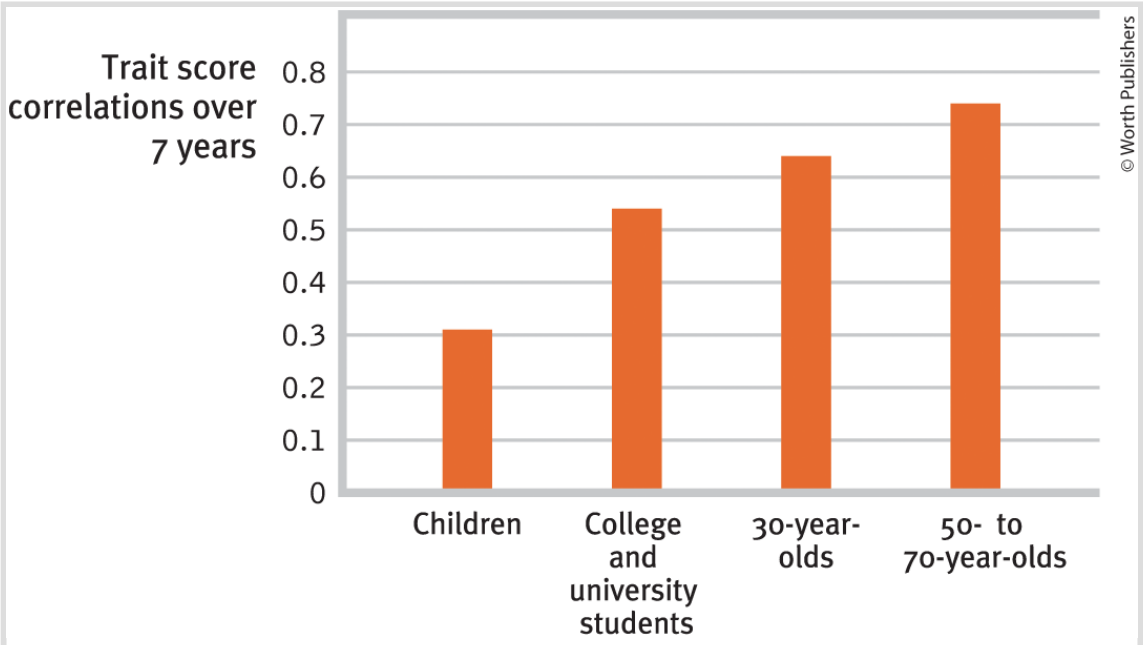

FIGURE 46.4 Personality stability With age, personality traits become more stable, as reflected in the stronger correlation of trait scores with follow-up scores 7 years later. (Data from Roberts & DelVecchio, 2000.)

So most people—including most psychologists—would probably presume the stability of personality traits. Moreover, our traits are socially significant. They influence our health, our thinking, and our job choices and performance (Hogan, 1998; Jackson et al., 2012; Mueller et al., 2018). Studies that follow thousands of lives through time show that personality traits rival socioeconomic status and

cognitive ability as predictors of mortality, divorce, and occupational attainment (Graham et al., 2017; Roberts et al., 2007).

Although our personality *traits* may be both stable and potent, the consistency of our specific *behaviors* from one situation to the next is another matter. What relationship would you expect to find between being conscientious in one situation (say, showing up for class on time) and being conscientious in another (say, avoiding unhealthy foods)? If you've noticed how outgoing you are in some situations and how reserved you are in others, perhaps you said, "Very little." That's what researchers have found—only a small correlation (Mischel, 1968; Sherman et al., 2015). This inconsistency in behaviors also makes personality test scores weak predictors of behaviors. People's scores on an extraversion test, for example, do not neatly predict how sociable they will be on any given occasion.

If we remember such results, we will be more cautious about labeling and pigeonholing individuals (Mischel, 1968). Years in advance, science can tell us the phase of the Moon for any date. A day in advance, meteorologists can predict the weather. But we are much further from being able to predict how *you* will feel and act tomorrow.

However, people's *average* outgoingness, happiness, or carelessness over many situations is predictable (Epstein, 1983a,b). This tendency toward trait-consistent actions occurs worldwide, from the United States to Venezuela to Japan (Locke et al., 2017). By tracking their daily phone activity, researchers confirmed that extraverts really do talk

and text more (Harari et al., 2020). I [DM] kept vowing to cut back on my jabbering and joking during my noontime pickup basketball games. Alas, moments later, the irrepressible chatterbox would inevitably reoccupy my body. Likewise, when buying groceries, I [ND] always end up chatting with the cashier! As our best friends can verify, we do have persistent (genetically influenced) personality traits. And our personality traits get expressed in our

- ***music preferences.*** Your playlist reveals something of your personality. Folk, classical, and ambient music lovers tend to be open to experience and verbally intelligent. Agreeable people tend to like jazz and avoid punk rock music. Blues, classic country, and soul music lovers tend to be emotionally stable. Extraverts like country music, R&B, and funk—and enjoy listening to their friends' playlists (Anderson et al., 2021). People also gravitate toward musicians who share their personality traits (Greenberg et al., 2021). Extraverts prefer extraverted Lil Wayne and Jay Z; agreeable people prefer the agreeable Norah Jones and Carrie Underwood.

- ***written communications.*** If you have ever felt you could detect someone's personality from their writing voice, you are right!! What a cool finding!!! 😊 People's writings—even their brief tweets and Facebook posts—often express their extraversion, self-esteem, and agreeableness (Bowden-Green et al., 2020; Park et al., 2015; Pennebaker, 2011). "Off to meet a friend. Woohoo!!!" posted one Facebook user who had scored high on extraversion (Kern et al., 2014). Extraverts also use more adjectives.

- ***online and personal spaces.*** Are online profiles, websites, and avatars a canvas for self-expression? Or are they an opportunity for people to present themselves in false or misleading ways? It's more the former (Akhtar et al., 2018; Hinds & Joinson, 2019). People who seemed most likable on Facebook or Twitter also seemed most likable in person (Qiu et al., 2012; Weisbuch et al., 2009). Photos show people's clothes, expressions, and postures, and can therefore give clues to personality and how people act in person (Gunyadin et al., 2017; Naumann et al., 2009). Our living and working spaces also help us express our identity, offering clues to our extraversion, agreeableness, conscientiousness, and openness (Back et al., 2010; Fong & Mar, 2015; Gosling, 2008).

"You tend to overuse the exclamation point."

In unfamiliar, formal situations (perhaps as a guest in the home of a person from another culture) our traits remain hidden as we carefully attend to social cues. In familiar, informal situations (just hanging out with friends), we feel less constrained, allowing our traits to emerge (Buss, 1989). In these informal situations, our expressive styles—our animation, manner of speaking, and gestures—are impressively consistent. Viewing "thin slices" of someone's behavior, such as seeing

a photo for a mere fraction of a second, or seeing several 2-second clips of a teacher in action, can tell us a lot about the person's basic personality traits (Ambady, 2010; Tackett et al., 2016).

Some people are naturally expressive (and therefore talented at pantomime and charades); others are less expressive (and therefore better poker players). To evaluate people's voluntary control over their expressiveness, Bella DePaulo and her colleagues (1992) asked people to *act* as expressive or inhibited as possible while stating opinions. Their remarkable findings: Inexpressive people, even when feigning expressiveness, were less expressive than expressive people acting naturally. Similarly, expressive people, even when trying to seem inhibited, were less inhibited than inexpressive people acting naturally. It's hard to be someone you're not, or not to be who you are.

James Woodson/Getty Images

Room with a cue Even at "zero acquaintance," people can catch a glimpse of others' personality from looking at their online and personal spaces. So, what's your read on the occupants of these two rooms?

To sum up, we can say that at any moment the immediate situation powerfully influences a person's behavior. Social psychologists have learned that this is especially so when a "strong situation" makes clear demands (Cooper & Withey, 2009). We can better predict drivers' behavior at traffic lights from knowing the color of the lights than from knowing the drivers' personalities. Thus, professors may perceive certain students as subdued (based on their classroom behavior), but friends may perceive them as pretty wild (based on their party behavior). Averaging our behavior across many occasions

does, however, reveal distinct personality traits. Traits exist. We differ. And our differences matter.

Ask Yourself

How do you think your own personality traits shine through in your music preferences, communication style, and online and personal spaces?

Module 46: Humanistic Theories and Trait Theories

Learning Objectives

Test Yourself Answer these repeated Learning Objective Questions on your own (before "showing" the answers here, or checking the answers in Appendix D) to improve your retention of the concepts (McDaniel et al., 2009, 2015).

LOQ 46-1: How did humanistic psychologists view personality, and what was their goal in studying personality?

LOQ 46-2: How did humanistic psychologists assess a person's sense of self?

LOQ 46-3: How have humanistic theories influenced psychology? What criticisms have they faced?

LOQ 46-4: How do psychologists use traits to describe personality?

LOQ 46-5: What are some common misunderstandings about introversion?

LOQ 46-6: What are *personality inventories,* and what are their strengths and weaknesses as trait-assessment tools?

LOQ 46-7: Which traits seem to provide the most useful information about personality variation?

LOQ 46-8: Does research support the consistency of personality traits over time and across situations?

Terms and Concepts to Remember

Test Yourself Write down the definition in your own words, then check your answer.

humanistic theories

hierarchy of needs
self-actualization
self-transcendence
unconditional positive regard
self-concept
trait
personality inventory
self-report
Minnesota Multiphasic Personality Inventory (MMPI)
empirically derived test
Big Five factors

Module Test

Test Yourself Answer the following questions on your own first, then "show" the answers here, or check your answers in Appendix E.

1. Maslow's hierarchy of needs proposes that we must satisfy basic physiological and safety needs before we seek ultimate psychological needs, such as self-actualization. Maslow based his ideas on
   a. Freudian theory.
   b. his experiences with patients.
   c. a series of laboratory experiments.

d. his study of healthy, creative people.

2. How might Rogers explain how environment influences the development of a criminal?

3. The total acceptance Rogers advocated as part of a growth-promoting environment is called _____ _____ _____.

4. _____ theories of personality focus on describing characteristic behavior patterns, such as agreeableness or extraversion.

5. The most widely used personality inventory is the
   a. Extraversion–Introversion Scale.
   b. Person-Situation Inventory.
   c. MMPI.
   d. Big Five.

6. Which of the following is NOT one of the Big Five personality factors?
   a. Conscientiousness
   b. Anxiety
   c. Extraversion
   d. Agreeableness

7. Our scores on personality tests best predict
   a. our behavior on a specific occasion.
   b. our average behavior across many situations.

MODULE 47: Social-Cognitive Theories and the Self

Roughly speaking, the outside influences on behavior are the focus of *social psychology* (see the Social Psychology modules), and the inner influences are the focus of *personality psychology.* But behavior always depends on the interaction of persons with situations.

Social-Cognitive Theories

LOQ 47-1

How do social-cognitive theorists view personality development, and how do they explore behavior?

The **social-cognitive perspective** on personality, proposed by Albert Bandura (1986, 2006, 2008), emphasizes the interaction of our traits with our social situations.

Social-cognitive theorists believe we learn many of our behaviors either through conditioning or by observing and imitating others. (That's the "social" part.) They also emphasize the importance of mental processes: What we *think* about a situation affects our resulting behavior. (That's the "cognitive" part.) Instead of focusing

solely on how our environment *controls* us (behaviorism), social-cognitive theorists focus on how we and our environment *interact:* How do we interpret and respond to external events? How do our schemas, our memories, and our expectations influence our behavior patterns?

Reciprocal Influences

Bandura (1986, 2006) views the person-environment interaction as **reciprocal determinism**. "Behavior, internal personal factors, and environmental influences," he said, "all operate as interlocking determinants of each other" (FIGURE 47.1). We can see this interaction as people's relationships affect their self-esteem, and as their self-esteem also affects their relationships (de Moor et al., 2021; Harris & Orth, 2020). For example, Rosa's past romantic experiences (her behaviors) influence her romantic attitudes (internal factor), which affect how she now responds to Ryan (environmental factor).

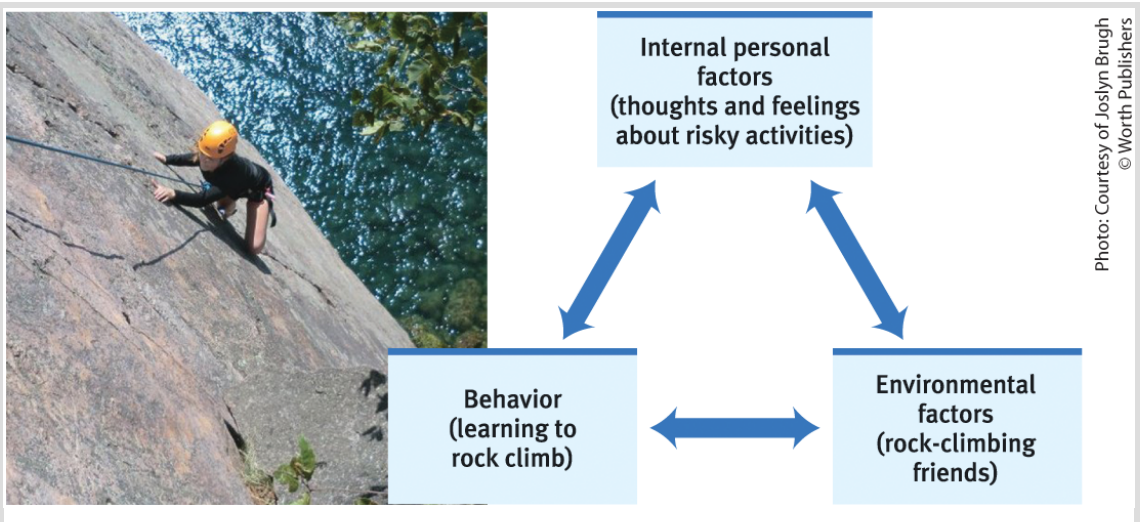

FIGURE 47.1 Reciprocal determinism

Consider three specific ways in which individuals and environments interact:

1. ***Different people choose different environments.*** The reading we do, the social media we use, the careers we pursue, the music we listen to, the friends we associate with—all are part of the environment we have chosen, based partly on our disposition (Denissen et al., 2018; Funder, 2009). And the environments we choose then shape us. People with inflated self-esteem may post frequent selfies, which may lead to public attention and praise, and to even greater self-love (Halpern et al., 2016).

2. ***Our personalities shape how we interpret and react to events.*** If we perceive the world as threatening, we will watch for threats and be prepared to defend ourselves. Anxious people often attend to and react strongly to relationship threats, such as when they feel ignored or excluded (Campbell & Marshall, 2011).

3. ***Our personalities help create situations to which we react.*** How we view and treat people influences how they then treat us. If we expect that others will not like us, our efforts to win their approval (such as bragging) might actually cause them to reject us (Scopelliti et al., 2015).

In addition to the interaction of internal personal factors, the environment, and our behaviors, we also experience *gene–environment*

interaction. Our genetically influenced traits evoke certain responses from others, which may nudge us in one direction or another. In one well-replicated finding, those with the interacting factors of (1) having a specific gene associated with aggression and (2) being raised in a difficult environment were most likely to demonstrate adult antisocial behavior (Byrd & Manuck, 2014; Caspi et al., 2002).

In such ways, we are both the products and the architects of our environments: *Behavior emerges from the interplay of external and internal influences.* Boiling water turns an egg hard and a potato soft. A threatening environment turns one person into a hero, another into a scoundrel. Extraverts experience focused concentration—what psychologists call *flow*—in social situations; introverts more often experience flow when alone (Liu & Csikszentmihalyi, 2020). *At every moment,* our behavior is influenced by our biology, our social and cultural experiences, and our cognition and dispositions (**FIGURE 47.2**).

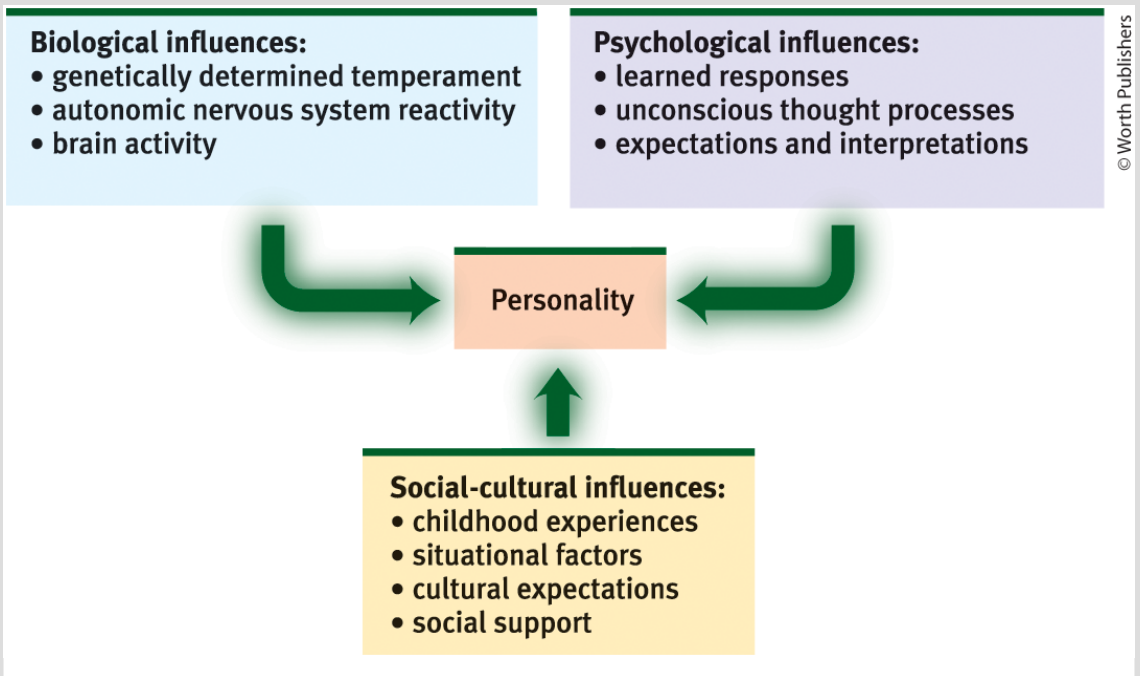

FIGURE 47.2 The biopsychosocial approach to the study of personality As with other psychological phenomena, personality is fruitfully studied at multiple levels.

Ask Yourself

How have your experiences shaped your personality? How has your personality helped shape your environment?

Retrieval Practice

RP-1 Albert Bandura proposed the _____-_____ perspective on personality, which emphasizes the interaction of people with their environment. To describe the interacting influences of behavior, thoughts, and environment, he used the term _____ _____.

ANSWERS IN APPENDIX E

Assessing Behavior in Situations

To predict behavior, social-cognitive psychologists often observe behavior in realistic situations. One ambitious example was the U.S. Army's World War II strategy for assessing candidates for spy missions. Rather than using paper-and-pencil tests, Army psychologists subjected the candidates to simulated undercover conditions. They tested their ability to handle stress, solve problems, maintain leadership, and withstand intense interrogation without blowing their cover. Although time-consuming and expensive, this assessment of behavior in a realistic situation helped predict later success on actual spy missions (OSS Assessment Staff, 1948).

Military and educational organizations and many Fortune 500 companies have adopted similar strategies, known as the *assessment center* approach (Bray & Byham, 1991, 1997; Eurich et al., 2009). The U.S. telecommunications giant AT&T has observed prospective managers doing simulated managerial work. Some European universities give student applicants material to study, and then test their learning—thus mimicking the educational program (Niessen & Meijer, 2017). Many colleges assess nursing students' potential by observing their clinical work. And they assess potential faculty members' teaching abilities by observing them teach.

Shutterstock

Teaching success Many education programs require students to complete a supervised instructional experience. The student teaching program presumes a valid point: People's behavior in job-relevant situations helps predict their job performance.

The assessment center approach exploits the principle that the best means of predicting behavior is neither a personality test nor an interviewer's intuition. Rather, *the best predictor of future behavior is the person's past behavior patterns in similar situations* (Lyons et al., 2011; Mischel, 1981; Schmidt & Hunter, 1998). As long as the situation and the person remain much the same, the best predictor of future job performance is past job performance; the best predictor of future grades is past grades; the best predictor of future aggressiveness is past aggressiveness. People who have used marital infidelity websites at home will also be more likely to behave immorally at work (Griffin et al., 2019). If you can't check the person's past behavior, the next best thing is to create an assessment situation that simulates the task so you can see how the person handles it (Lievens et al., 2009; Meriac et al., 2008).

"What's past is prologue." — William Shakespeare, *The Tempest,* 1611

Evaluating Social-Cognitive Theories

LOQ 47-2

What criticisms have social-cognitive theories faced?

Social-cognitive theories of personality sensitize researchers to how situations affect, and are affected by, individuals. More than other personality theories (see TABLE 47.1), they build from psychological research on learning and cognition.

TABLE 47.1 Comparing the Major Personality Theories

Personality Theory	Key Proponents	Assumptions	View of Personality	Personality Assessment Methods
Psychoanalytic	Freud	Emotional disorders spring from unconscious dynamics, such as unresolved sexual and other childhood conflicts, and fixation at various	Personality consists of pleasure-seeking impulses (the id), a reality-oriented executive (the ego), and an internalized set of ideals (the superego).	Free association, projective tests, dream analysis

		developmental stages. Defense mechanisms fend off anxiety.		
Psychodynamic	Adler, Horney, Jung	The unconscious and conscious minds interact. Childhood experiences and defense mechanisms are important.	The dynamic interplay of conscious and unconscious motives and conflicts shapes our personality.	Projective tests, therapy sessions
Humanistic	Maslow, Rogers	Rather than focusing on disorders born of dark conflicts, it's better to emphasize how healthy people may strive for self-realization.	If our basic human needs are met, we will strive toward self-actualization. In a climate of unconditional positive regard, we can develop self-awareness and a more realistic and positive self-concept.	Questionnaires, therapy sessions, life story approach
Trait	Allport; Costa; H. Eysenck; S. Eysenck; McCrae	We have certain stable and enduring characteristics, influenced by genetic predispositions.	Scientific study of traits has isolated important dimensions of personality, such as the Big Five traits (openness, conscientiousness, extraversion,	Personality inventories

			agreeableness, and neuroticism).	
Social-cognitive	Bandura	Our traits interact with the social context to produce our behaviors.	Conditioning and observational learning interact with cognition to create behavior patterns. Our behavior in one situation is best predicted by considering our past behavior in similar situations.	Observing behavior in realistic situations

Critics charge that social-cognitive theories focus so much on the situation that they fail to appreciate the person's inner traits. Where is the person in this view of personality, ask the dissenters, and where are human emotions? True, the situation does guide our behavior. But in many instances our unconscious motives, our emotions, and our pervasive traits shine through. Personality traits predict behavior at work, in love, and at play. Our biologically influenced traits really do matter. Consider Percy Ray Pridgen and Charles Gill. Each faced the same situation: They had jointly won a $90 million lottery jackpot (Harriston, 1993). When Pridgen learned of the winning numbers, he began trembling uncontrollably, huddled with a friend behind a bathroom door while confirming the win, and then sobbed. When Gill heard the news, he told his wife and then went to sleep.

RP-2 What is the best way to predict a person's future behavior?

ANSWERS IN APPENDIX E

Exploring the Self

LOQ 47-3

Why has psychology generated so much research on the self?

Our personality feeds our sense of self. Asked to consider "Who I am," people draw on their distinctive and enduring ways of thinking, feeling, and acting. Psychology's concern with our sense of self dates back at least to William James, who devoted more than 100 pages of his 1890 *Principles of Psychology* to the topic. By 1943, Gordon Allport lamented that the self had become "lost to view." Although humanistic psychology's later emphasis on the self did not instigate much scientific research, it did help renew the concept of self and keep it alive. Now, more than a century after James, the self is one of Western psychology's most vigorously researched topics. Every year, new studies galore appear on self-esteem, self-disclosure, self-awareness, self-schemas, self-monitoring, and more. Even neuroscientists have searched for the self, by identifying a central frontal lobe region that activates when people respond to self-reflective questions about their

traits and dispositions (Damasio, 2010; Mitchell, 2009; Pauly et al., 2013). The **self**, as organizer of our thoughts, feelings, and actions, occupies the center of personality.

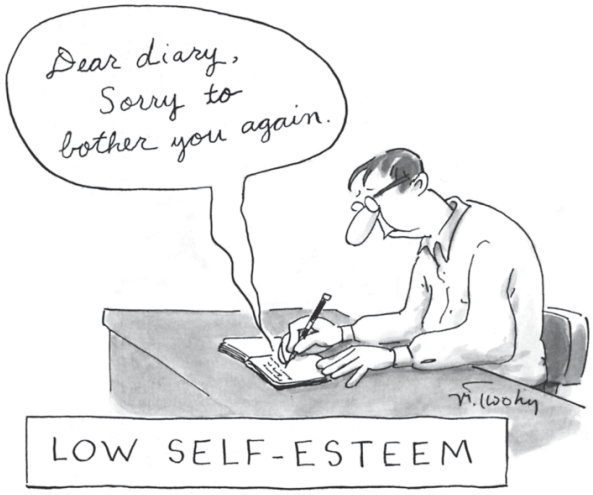
Consider the concept of *possible selves* (Markus & Nurius, 1986; Rathbone et al., 2016). Your possible selves include your visions of the self you dream of becoming (the rich self, the successful self, the loved and admired self), and also the self you fear becoming (the unemployed self, the academically failed self, the lonely and unpopular self). Possible selves motivate us to lay out specific goals that direct our energy effectively and efficiently (Landau et al., 2014). Eighth- and ninth-grade students whose families struggle financially are more likely to earn high grades if they have a clear vision of themselves succeeding in school (Duckworth et al., 2013). Dreams do often give birth to achievements.

Our self-focused perspective may motivate us, but it can also lead us to presume too readily that others are noticing and evaluating us, a phenomenon called the **spotlight effect**. In one experiment, university students who were asked to put on an embarrassing T-shirt before meeting other students guessed that nearly half their peers would notice the shirt. But only 23 percent did (Gilovich, 1996). To turn down the spotlight's brightness, we can use two strategies. The first is simply to know and remember the spotlight effect. Public speakers perform better if they understand that their natural nervousness is hardly noticeable (Savitsky & Gilovich, 2003). The second is to take the audience's perspective. When we imagine

audience members empathizing with our situation, we usually expect to be judged less harshly (Epley et al., 2002). The point to remember: *We stand out less than we imagine,* even with dorky clothes and bad hair, and even after a blunder like setting off a library alarm (Gilovich & Savitsky, 1999; Savitsky et al., 2001).

Ask Yourself

What possible selves do you dream of—or fear—becoming? To what extent do these imagined selves motivate you now?



The Benefits of Self-Esteem

LOQ 47-4

How important is self-esteem to our well-being?

Self-esteem—our feelings of high or low self-worth—matters. So does **self-efficacy**, our sense of competence on a task (Bandura, 1977, 2018). (A student might feel high self-efficacy in a math course yet low overall self-esteem.) People who feel good about themselves (who strongly agree with self-affirming questionnaire statements, such as "I am fun to be with") have fewer sleepless nights. They tend to be outgoing, responsible, and open to new experiences (Fetvadjiev & He, 2019). Online and in person, they communicate positively, causing others to like and include them more (Cameron & Granger, 2019;

Mahadevan et al., 2019). They feel less shy, anxious, and lonely, and are just plain happier (Greenberg, 2008; Orth & Robins, 2014; Swann et al., 2007). Our self-esteem grows from venturesome experiences and achievement, and therefore changes as we age (Hutteman et al., 2015). Self-esteem often increases dramatically from adolescence to middle adulthood, continuing to climb until peaking between ages 50 and 60 (Bleidorn et al., 2016; Orth et al., 2018; von Soest et al., 2018).

Mike Twohy/Cartoon Stock

But most psychologists doubt that high self-esteem is "the armor that protects kids" from life's problems (Baumeister & Vohs, 2018; McKay, 2000; Seligman, 2002). Children's academic self-efficacy—their confidence that they can do well in a subject—predicts school achievement. But general self-image does not (Marsh & Craven, 2006; Swann et al., 2007; Trautwein et al., 2006). Maybe self-esteem is a side effect of meeting challenges and surmounting difficulties, or a gauge that reports the state of our relationships with others (Bleidorn et al., 2021; Reitz et al., 2016). If so, isn't pushing the gauge artificially higher

with empty compliments much like forcing a car's low fuel gauge to display "full"?

> **"When kids increase in self-control, their grades go up later. But when kids increase their self-esteem, there is no effect on their grades."** — Angela Duckworth, *In Character* interview, 2009

If feeling good *follows* doing well, then giving praise in the absence of good performance may actually harm people. After receiving weekly self-esteem-boosting messages, struggling students earned *lower*-than-expected grades (Forsyth et al., 2007). Other research showed that giving people random rewards hurt their productivity. Martin Seligman (2012) reported that "when good things occurred that weren't earned, like nickels coming out of slot machines, it did not increase people's well-being. It produced helplessness. People gave up and became passive."

> **"The enthusiastic claims of the self-esteem movement mostly range from fantasy to hogwash. The effects of self-esteem are small, limited, and not all good."** — Roy Baumeister (1996)

There are, however, important effects when self-esteem is threatened. When researchers temporarily deflated people's self-image (by telling them they did poorly on an aptitude test or by disparaging their personality), those participants became more likely to disparage

others or to express heightened racial prejudice (vanDellen et al., 2011; van Dijk et al., 2011; Ybarra, 1999). Self-image threat even increases *unconscious* racial bias (Allen & Sherman, 2011). Those who are negative about themselves have also tended to be oversensitive and judgmental (Baumgardner et al., 1989; Pelham, 1993). Such findings are consistent with humanistic psychology's ideas about the benefits of a healthy self-image. Accept yourself and you'll find it easier to accept others. Disparage yourself and you will be prone to the floccinaucinihilipilification[2] of others. People who are down on themselves tend to be down on others.

The Costs of Self-Esteem

LOQ 47-5

How do excessive optimism, blindness to one's own incompetence, and self-serving bias reveal the costs of self-esteem, and how do defensive and secure self-esteem differ?

Excessive Optimism

Positive thinking in the face of adversity can pay dividends, but so, too, can a dash of realism (Schneider, 2001). Realistic anxiety over possible future failures can fuel energetic efforts to avoid the dreaded fate (Goodhart, 1986; Norem, 2001; Showers, 1992). Concerned about failing an upcoming exam, students may study thoroughly and outperform their equally able but more confident peers. Asian American students have expressed somewhat greater pessimism than

their European American counterparts, which may help explain their often impressive academic achievements (Chang, 2001). Success requires enough optimism to provide hope and enough pessimism to prevent complacency. We want our airline pilots to be mindful of worst-possible outcomes.

Excessive optimism can blind us to real risks (Tenney et al., 2015). More than 1000 studies have shown how our natural positive thinking bias can promote "unrealistic optimism" (Shepperd et al., 2015; Weinstein, 1980). When 56 percent of twelfth graders believed they would earn a graduate degree—though only 9 percent were likely to do so—that was unrealistic optimism (Reynolds et al., 2006). When most people of opposing political views optimistically believed that *their* views would become more widely held, many were in error (Rogers et al., 2017). When students believed they were more likely than their classmates to get a high-paying job and own a nice home, and less likely to have a heart attack or get cancer, that, too, was unrealistic optimism (Waters et al., 2011). If overconfident of our ability to control an impulse such as the urge to smoke, we are more likely to expose ourselves to temptations—and to fail (Nordgren et al., 2009). Blind optimism can be self-defeating, as we can see in those who optimistically deny the addictive toxicity of smoking, venture into ill-fated relationships, and invest money in risky schemes.

Our natural positive thinking bias does seem to vanish, however, when we are awaiting feedback, such as exam results (Carroll et al., 2006). Across many studies in both the real world (awaiting bar exam

scores) and laboratory (awaiting intelligence test results), people "brace for the worst" (Sweeny & Falkenstein, 2017). (Perhaps you, too, can recall shifting toward pessimism as a moment of truth approaches?) Positive illusions also vanish after a traumatic personal experience—as they did for victims of a catastrophic California earthquake, who had to give up their illusions of being less vulnerable than others to earthquakes (Helweg-Larsen, 1999).

Blindness to One's Own Incompetence

Ironically, people often are most overconfident when most incompetent. They are often "unskilled and unaware of it," observed Justin Kruger and David Dunning (1999), after finding that most students scoring at the low end of grammar and logic tests *believed* they had scored in the top half. This "ignorance of one's own incompetence," now famously called the *Dunning-Kruger effect,* can produce overconfidence among political leaders. It also has a parallel among those of us with hearing loss, as I [DM] can confirm. Because we are unaware of what we don't hear, we may overestimate our hearing. If I fail to hear my friend calling my name, the friend notices my inattention. But for me it's a nonevent. I hear what I hear—which, to me, seems pretty normal. As comedian Trevor Noah (2020) quipped, "This is the problem when the dumbest person in the room thinks they're the smartest."

"What I'd dearly love would be to be able to see [myself] having a Dunning-Kruger moment. But according to my own theory, I'll never have it." —

> Psychologist David Dunning, NPR, 2016

Because it takes competence to recognize competence, "Our ignorance is invisible to us," summarizes Dunning (2019). "The first rule of the Dunning-Kruger club," he says, "is you don't know you're a member of the Dunning-Kruger club." Thus, to judge our competence and predict our future performance, it pays to invite others' assessments (Dunning, 2006; Grossmann & Kross, 2014).

Based on studies in which both individuals and their acquaintances predict their future, we can hazard some advice: Ask your peers for their candid prediction. If you're in love and want to predict whether it will last, don't listen to your heart—ask your roommate.

Self-Serving Bias

Imagine dashing to class, hoping not to miss the first few minutes. But you arrive 5 minutes late, huffing and puffing. As you sink into your seat, what sorts of thoughts go through your mind? Do you go through a negative door, thinking "I'm such a loser"? Or do you go through a positive door, telling yourself, "At least I made it to class"?

Personality psychologists have found that most people choose the second door because it leads to positive self-thoughts. We have a good reputation with ourselves. We show a **self-serving bias**—a readiness to perceive ourselves favorably (Myers, 2010). Consider:

People accept more responsibility for good deeds than for bad, and for successes than for failures. Athletes often privately credit their victories to their own prowess, and their losses to bad breaks, lousy officiating, or the other team's exceptional performance (Allen et al., 2020). Most students who receive poor exam grades criticize the exam or the instructor, not themselves. Drivers filling out insurance claims have explained their accidents in such words as "A pedestrian hit me and went under my car." The question "What have I done to deserve this?" is one we usually ask of our troubles, not our successes. Although a self-serving bias can lead us to avoid uncomfortable truths, it can also motivate us to approach difficult tasks with confidence instead of despair (Tomaka et al., 1992; von Hippel & Trivers, 2011). Indeed, across many studies, self-enhancement predicts emotional well-being (Dufner et al., 2019).

Sophia Warren/Cartoon Stock

"That's strange. I remember it differently, in a way that aligns with my world view and casts me in a positive light."

Most people see themselves as better than average. Compared with most other people, how intelligent are you? How friendly? On each question, where would you rank yourself, from the 1st to the 99th percentile? Most people put themselves well above the 50th

percentile. This better-than-average effect appears for nearly any subjectively assessed and socially desirable trait or behavior. Most people rate themselves as having above average intelligence, kindness, humor, and ethics (Zell et al., 2020). Nine in ten drivers rate themselves as more skilled than the average driver (Koppel et al., 2021). Most people in the United Kingdom, the United States, and Germany believed that, compared with other same-aged citizens, they had a better-than-average chance of not catching Covid-19 (Kuper-Smith et al., 2020). The average person thinks they're better than average. Self-serving bias is weaker in Asia, where social practices emphasize modesty (Church et al., 2014; Falk et al., 2009). Yet in every one of 53 countries surveyed, people expressed self-esteem above the midpoint of the most widely used scale (Schmitt & Allik, 2005).

"Fun fact: The average man [thinks] he would be better than 63 percent of other men if he had to survive a zombie apocalypse." — Mathematician Spencer Greenberg and economist Seth Stephens-Davidowitz, 2019

Self-serving bias often underlies conflicts, such as blaming a partner for relationship problems or a colleague for work problems. All of us also tend to see our own *groups*—our school, organization, region, or country—as superior. Although there are 50 U.S. states, Americans on average estimate that their home state made 18 percent of the contributions to U.S. history (Putnam et al., 2018). Likewise, people from 35 countries rate their own country as making outsized contributions to world history (Zaromb et al., 2018). Such *group-serving bias*—my group is better—fueled the trans-Atlantic slave trade, Nazi horrors, and Rwandan genocide. No wonder literature and religion so often warn against the perils of self-love and pride. Ingroup love often feeds outgroup hate (Golec de Zavala & Lantos, 2020).

Finding their self-esteem threatened, some people with inflated egos may react violently. Researchers Brad Bushman and Roy Baumeister (1998; Bushman et al., 2009) had undergraduate volunteers write a brief essay, in response to which another supposed student gave them either praise ("Great essay!") or stinging criticism ("One of the worst essays I have read!"). The essay writers were then allowed to lash out at their evaluators by blasting them with unpleasant noise. Can you anticipate the result? After criticism, those with inflated self-esteem were "exceptionally aggressive." They delivered three times the auditory torture than did those with average self-esteem. Over 80 studies have replicated the dangerous effect of **narcissism** (excessive self-love and self-focus) on aggression (Rasmussen, 2016). Researchers have concluded that "conceited, self-important individuals turn nasty

toward those who puncture their bubbles of self-love" (Baumeister, 2001).

After tracking self-importance across several decades, psychologist Jean Twenge (2006; Twenge & Foster, 2010) reported that what she called *Generation Me*—born in the 1980s and early 1990s—expressed more narcissism (by agreeing more often with statements such as, "If I ruled the world, it would be a better place," or "I think I am a special person"). Why does a rise in narcissism matter? Narcissists tend to be materialistic, desire fame, have inflated expectations, hook up more often without commitment, and gamble and cheat more—all of which have been increasing as narcissism has increased. Humility, by contrast, is the attitude that, no matter your accomplishments, you are not entitled to special treatment (Banker & Leary, 2020).

Narcissistic people (who are more often men) tend to be unforgiving, take a game-playing, sexually forceful approach to romantic relationships, and are more likely to become divorced (Johnson, 2020; Lamarche & Seery, 2019; Wetzel et al., 2020). They're often charismatic and ambitious, making them popular until others tire of their cold-hearted arrogance (Leckelt et al., 2020; Poorthuis et al., 2019). From moment to moment, they crave status and adulation and often become defensive or enraged when criticized (Grapsas et al., 2020; Sedikides, 2021). Many had parents who told them they were superior to others (Brummelman et al., 2015). Reality TV stars are often especially narcissistic (Rubinstein, 2016; Young & Pinsky, 2006).

> **"The [self-]portraits that we actually believe, when we are given freedom to voice them, are dramatically more positive than reality can sustain."** — Shelley Taylor, *Positive Illusions,* 1989

Despite the demonstrated perils of pride, many people object that the idea of self-serving bias overlooks those who feel worthless and unlovable. If self-serving bias prevails, why do so many people disparage themselves? For five reasons:

1. Sometimes self-directed put-downs are *subtly strategic*—they elicit reassuring strokes. Saying "No one likes me" may at least elicit "But not everyone has met you!"
2. Other times, such as before a game or an exam, self-disparaging comments *prepare us for possible failure.* The coach who extols the superior strength of the upcoming opponent makes a loss understandable, a victory noteworthy.
3. A self-disparaging "How could I have been so stupid!" also helps us *learn from our mistakes.*
4. Sometimes false humility is actually a *humblebrag:* "I barely studied, so I'm amazed I got an A" (Sezer et al., 2018).
5. Self-disparagement frequently *pertains to one's old self.* Asked to remember their really bad behaviors, people recall things from long ago; good behaviors more easily come to mind from their recent past (Escobedo & Adolphs, 2010). Even when they have not changed, people are much more critical of their distant past selves than of their current selves (Wilson & Ross, 2001). Chumps

yesterday, champs today: “At 18, I was a jerk; today I’m more sensitive.”

Even so, all of us some of the time (and some of us much of the time) do feel inferior. This is especially true when we compare ourselves with those who are a step or two higher on the ladder of status, looks, income, or ability. The more frequently we feel comparatively inferior, the more unhappy or even depressed we become. But for most people, thinking has a naturally positive bias.

> **“If you compare yourself with others, you may become vain and bitter; for always there will be greater and lesser persons than yourself.”** — Max Ehrmann, “Desiderata,” 1927

Some researchers identify two types of self-esteem—defensive and secure (Kernis, 2003; Lambird & Mann, 2006; Ryan & Deci, 2004). *Defensive self-esteem* is fragile. It focuses on sustaining itself, which makes failure and criticism feel threatening. Defensive people may respond to such perceived threats with anger or aggression (Crocker & Park, 2004; Donnellan et al., 2005).

Secure self-esteem is less fragile, because it is less contingent on external evaluations. To feel accepted for who we are, and not for our looks, wealth, or acclaim, relieves pressures to succeed and enables us to focus beyond ourselves. Those who accept their own flaws also more compassionately accept others’ flaws (Zhang et al., 2020).

By losing ourselves in relationships and purposes larger than ourselves, we may achieve a more secure self-esteem, satisfying relationships, and greater quality of life (Crocker & Park, 2004). Authentic pride, rooted in actual achievement, supports self-confidence and leadership (Tracy et al., 2009; Weidman et al., 2016; Williams & DeSteno, 2009).

"True humility is not thinking less of yourself; it is thinking of yourself less." — C. S. Lewis, *Mere Christianity,* 1952

Retrieval Practice

RP-3 What are the positive and negative effects of high self-esteem?

RP-4 The tendency to accept responsibility for success and blame circumstances or bad luck for failure is called _____-_____ _____.

RP-5 _____ (Secure/Defensive) self-esteem is linked to angry and aggressive behavior. _____ (Secure/Defensive) self-esteem is a healthier self-image that allows us to focus beyond ourselves and enjoy a higher quality of life.

Module 47: Social-Cognitive Theories and the Self

Learning Objectives

Test Yourself Answer these repeated Learning Objective Questions on your own (before "showing" the answers here, or checking the answers in Appendix D) to improve your retention of the concepts (McDaniel et al., 2009, 2015).

LOQ 47-1: How do social-cognitive theorists view personality development, and how do they explore behavior?

LOQ 47-2: What criticisms have social-cognitive theories faced?

LOQ 47-3: Why has psychology generated so much research on the self?

LOQ 47-4: How important is self-esteem to our well-being?

LOQ 47-5: How do excessive optimism, blindness to one's own incompetence, and self-serving bias reveal the costs of self-esteem, and how do defensive and secure self-esteem differ?

Terms and Concepts to Remember

Test Yourself Write down the definition in your own words, then check your answer.

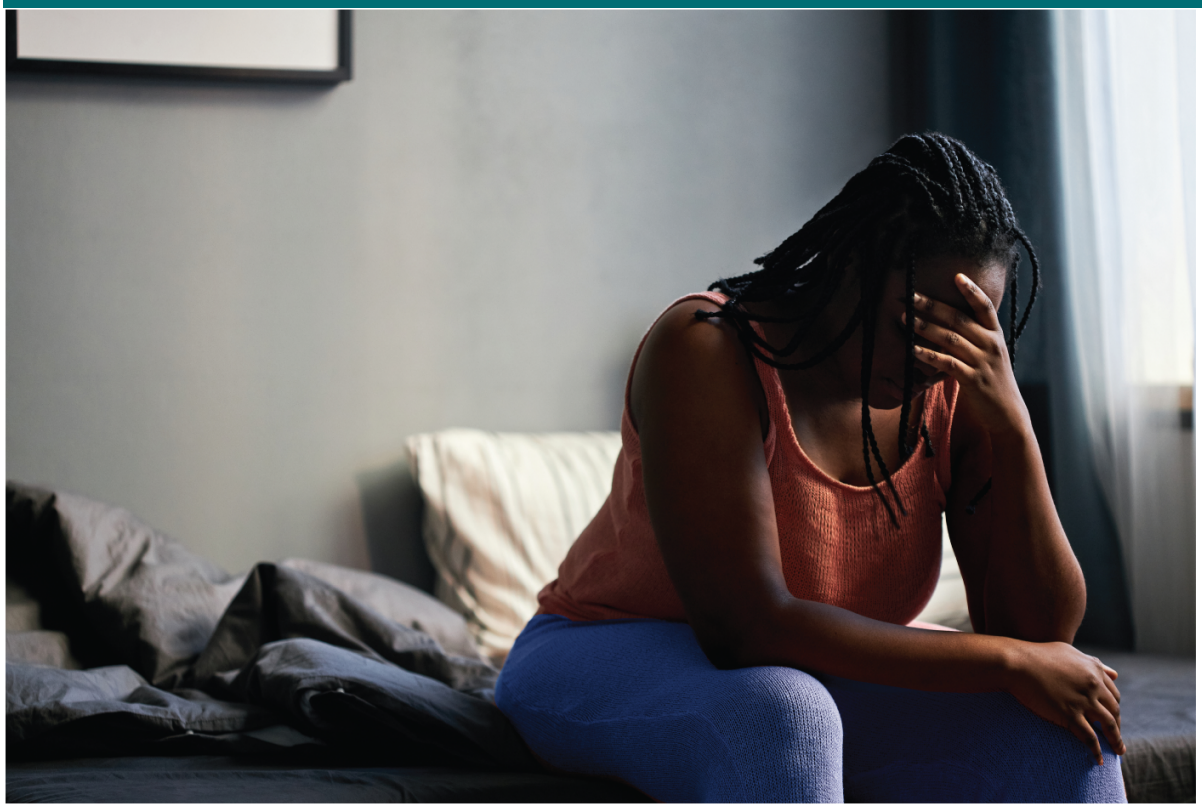
social-cognitive perspective
reciprocal determinism
self
spotlight effect
self-esteem
self-efficacy
self-serving bias
narcissism

Module Test

Test Yourself Answer the following questions on your own first, then "show" the answers here, or check your answers in Appendix E.

1. The social-cognitive perspective proposes our personality is shaped by a process called *reciprocal determinism,* as personal factors, environmental factors, and behaviors interact. An example of an environmental factor is
   a. the presence of books in a home.

b. a preference for outdoor play.
c. the ability to read at a fourth-grade level.
d. the fear of violent action on television.



2. Critics say that _____-_____ personality theories are very sensitive to an individual's interactions with particular situations, but that they give too little attention to the person's enduring traits.

3. The tendency to overestimate others' attention to and evaluation of our appearance, performance, and blunders is called the _____ _____.

4. Researchers have found that low self-esteem tends to be linked with life problems. How should this link be interpreted?
   a. Life problems cause low self-esteem.
   b. The answer isn't clear because the link is correlational and does not indicate cause and effect.
   c. Low self-esteem leads to life problems.
   d. Because of the self-serving bias, we must assume that external factors cause low self-esteem.

5. A fortune cookie advises, "Love yourself and happiness will follow." Is this good advice?

Autism Spectrum Disorder
Attention-Deficit/Hyperactivity Disorder
THINKING CRITICALLY ABOUT: ADHD—Natural High Energy or Disordered Behavior?

> You lose entire blocks of your day to obsessive thoughts or actions. I spend so much time finishing songs in my car before I can get out or redoing my entire shower routine because I lost count of how many times I scrubbed my left arm.
>
> *Kelly, diagnosed with obsessive-compulsive disorder (from Schuster, 2015)*

> Whenever I get depressed it's because I've lost a sense of self. I can't find reasons to like myself. I think I'm ugly. I think no one likes me.
>
> *Greta, diagnosed with depression (from Thorne, 1993, p. 21)*

> Voices, like the roar of a crowd, came. I felt like Jesus; I was being crucified.
>
> *Stuart, diagnosed with schizophrenia (from Emmons et al., 1997)*

Now and then, we all feel, think, or act in ways that resemble a psychological disorder. We feel anxious, depressed, withdrawn, or suspicious. So it's no wonder we are drawn to try to understand disordered psychological states—we sometimes see ourselves in the mental illnesses we study.

Worldwide, nearly a billion people live with mental or behavioral disorders (GBD, 2022). Many of us will know—or love someone who knows—the bewilderment and pain of unexplained physical symptoms,

irrational fears, or a feeling that life is not worth living. In a survey of first-year university students in eight countries, 1 in 3 reported a mental health problem during the prior year (Auerbach et al., 2018).

Each year, mental or behavioral disorders contribute to an estimated 8 million deaths (Walker et al., 2015). Although their rates and symptoms vary by culture, no known society is free of two serious disorders—*major depressive disorder* and *schizophrenia* (Baumeister & Härter, 2007; Jablensky, 1999; Susser & Martínez-Alés, 2018). These modules examine mental disorders; the Therapy modules consider scientifically-studied treatments for them.

MODULE 48: Introduction to Psychological Disorders

Most people would agree that someone who is depressed and stays mostly in bed for 3 months has a psychological disorder. But what about a grieving father who, 3 months after his child has died, can't resume his usual social activities? Where should we draw the line between understandable grief and clinical depression? Between a fear and a phobia? Between typical distractedness and attention-deficit/hyperactivity disorder?

> **"Who in the rainbow can draw the line where the violet tint ends and the orange tint begins? Distinctly we see the difference of the colors, but where exactly does the one first blendingly enter into the other? So with sanity and insanity."** — Herman Melville, *Billy Budd, Sailor,* 1924

And how do race and socioeconomic status influence mental illness diagnoses and treatment? For example, why are incarcerated people in the United States more likely to receive a mental health diagnosis if they are White, whereas those who are Black are more likely to be labeled merely as criminals (Bronson & Berzofsky, 2017; Prins et al., 2012)? Why are White defendants more often offered substance use disorder treatment as an alternative to prosecution, while Black defendants in similar circumstances more often receive a felony

conviction (Schlesinger, 2013)? And why do people in poverty have an increased risk for depression and anxiety—and often struggle for equitable access to high-quality mental health care (Hodgkinson et al., 2017; Ridley et al., 2020)? Scientists and clinicians are asking these and other questions:

- How should we *define* psychological disorders?
- How should we *understand* what causes disorders? How do underlying biological factors contribute? How do troubling environments influence our well-being? And how do these effects of nature and nurture interact?
- How should we *classify* psychological disorders? And can we do so in a way that allows us to help people without stigmatizing or labeling them?
- Are those with psychological disorders at risk of harming themselves or others?
- What do we know about rates of psychological disorders? How many people have them? Who is vulnerable, and when are they most likely to develop a new disorder?

Defining Psychological Disorders

Learning Objective Question LOQ 48-1

How should we draw the line between typical behavior and a disorder?

A **psychological disorder** is a syndrome (a collection of symptoms) marked by a "clinically significant disturbance in an individual's cognition, emotion regulation, or behavior" (American Psychiatric Association, 2013). Thoughts, emotions, or behaviors are described as *dysfunctional* or *maladaptive* when they interfere with day-to-day quality of life. Believing your home must be thoroughly cleaned every weekend is not a disorder; but if compulsive daily cleaning rituals interfere with work and leisure, they may indicate a disorder. Occasional sadness is to be expected; sadness that persists for weeks and becomes disabling likewise signals a psychological disorder. Feeling energized is common; feeling so hyped or excited that you sleep too little, drive dangerously, or spend money recklessly—perhaps worrying your loved ones—can be a sign of a disorder.

Distress often accompanies such dysfunction. Kelly, Greta, and Stuart were all distressed by their thoughts, emotions, or behaviors.

Over time, definitions of what constitutes a "significant disturbance" have varied. In 1973, the American Psychiatric Association voted that "homosexuality" should no longer be classified as a psychological disorder. The organization made this change because more and more of its members viewed same-sex attraction as a natural biological predisposition that did not cause people distress or impair their daily lives. Such is the power of shifting societal beliefs. Despite cultural progress toward reducing stigma and prejudice toward various groups, U.S. children and adolescents who identify as transgender or gender nonconforming have been seven times more likely than their

peers to be diagnosed with a psychological disorder (Becerra-Culqui et al., 2018). This is due largely to the continued stigma and stress they often experience (Hatzenbuehler et al., 2009; Meyer, 2003). In the twenty-first century, controversies swirl over other new or altered diagnoses in the most recent edition of psychiatry's manual for describing disorders (Conway et al., 2019; Widiger et al., 2019).

Retrieval Practice

RP-1 Anika, a lawyer, is distressed by feeling the need to wash her hands 100 times a day. She has little time to meet with clients, and her colleagues are wondering about her competence. Her behavior would probably be labeled disordered, because it is _____—that is, it interferes with her quality of life.

ANSWERS IN APPENDIX E

Understanding Psychological Disorders

LOQ 48-2

How do the medical model and the biopsychosocial approach influence our understanding of psychological disorders?

The way we view a problem influences how we try to solve it. In earlier times, people often viewed strange behaviors as evidence of strange forces at work—the movements of the stars, godlike powers, or evil spirits. Had you lived during the Middle Ages, you might have

said, “The devil made me do it.” Believing that, you might have approved of a harsh cure that would drive out the evil demon. Thus, people experiencing “madness” (as mental illness was then known) have been caged or given “therapies” such as genital mutilation, beatings, removal of teeth or lengths of intestines, or transfusions of animal blood (Farina, 1982).

John W. Verano

Yesterday’s “therapy”? Through the ages, people with psychological disorders have endured brutal treatments, including the trephination evident in this Stone Age patient’s skull. Drilling skull holes like these may have been an attempt to release evil spirits and cure those with psychological disorders. Do you think a patient would have

survived this kind of "cure"?

Reformers, such as Philippe Pinel (1745–1826) in France, opposed such brutal treatments. Madness is not demonic possession, Pinel insisted, but a sickness of the mind caused by severe stress and inhumane conditions. He argued that curing the illness requires *moral treatment,* including boosting patients' spirits by unchaining them and talking with them. He and others worked to replace brutality with gentleness, isolation with activity, and filth with clean air and sunshine.

In some places, cruel treatments for mental illness—including chaining people to beds or confining them in spaces with wild animals—linger even today. The World Health Organization has launched a reform that aims to transform hospitals "into patient-friendly and humane places with minimum restraints" (WHO, 2014).

The Medical Model

A medical breakthrough around the year 1900 prompted further reforms. Researchers discovered that syphilis, a sexually transmitted infection, invades the brain and distorts the mind. This discovery triggered an eager search for physical causes and effective treatments of other mental disorders. Hospitals replaced asylums, and the **medical model** of mental disorders was born. A mental *illness* (also called a psycho*pathology*) needs to be *diagnosed* based on its *symptoms.*

It needs to be *treated* through *therapy,* which may include time in a psychiatric *hospital.* Recent discoveries have energized the medical model, demonstrating that many genes together influence the brain and that biochemical abnormalities contribute to all major disorders (Smoller, 2019). A growing number of clinical psychologists work in medical hospitals, where they collaborate with physicians.

The Biopsychosocial Approach

To call psychological disorders "sicknesses" tilts research toward the influence of biology. But as in so many other areas, biological, psychological, and social-cultural influences together weave the fabric of our human experience. As individuals, we differ in how much stress we experience and how we cope with stressors. Cultures also differ in their sources of stress and in their ways of coping. We are physically embodied and socially embedded.

Two disorders—major depressive disorder and schizophrenia—occur worldwide. Other disorders tend to be associated with specific cultures. In Latin America, some experience *susto*—severe anxiety or panic in response to emotional trauma or fear of black magic. In Japanese culture, people may experience *taijin kyofusho*—social anxiety about physical appearance, a readiness to blush, and a fear of eye contact. The eating disorders *anorexia nervosa* and *bulimia nervosa* occur mostly in food-abundant Western cultures. These varied disorders may share an underlying dynamic (such as anxiety) while

differing in the symptoms (an eating problem or a specific fear) manifested in a particular culture.

The biopsychosocial approach emphasizes that mind and body are inseparable (FIGURE 48.1). Negative emotions can trigger physical problems and vice versa. The biopsychosocial approach gave rise to the *vulnerability-stress model,*[1] which assumes that individual dispositions combine with environmental stressors to influence psychological disorder (Monroe & Simons, 1991; Zuckerman, 1999). Research on **epigenetics** supports the vulnerability-stress model by showing how environment interacts with our DNA. A gene may be *expressed* in one environment, but not in another. For some, that will be the difference between developing a disorder or not.

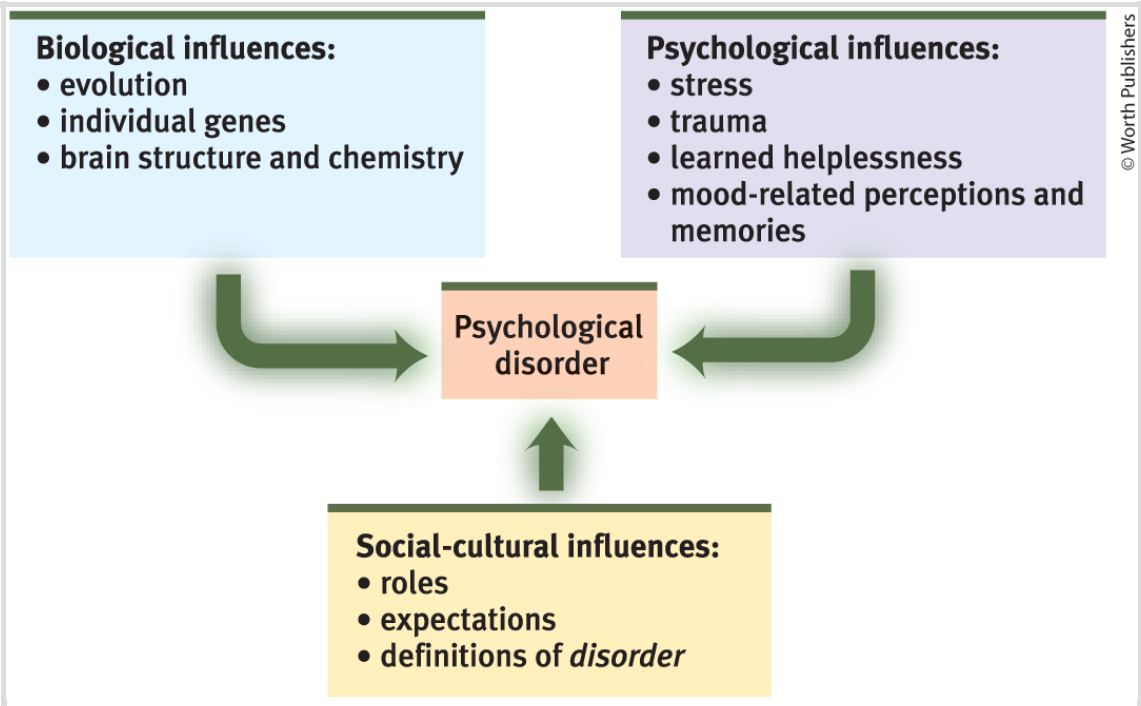

FIGURE 48.1 The biopsychosocial approach to psychological disorders Today's psychology studies how biological, psychological, and social-cultural factors interact to

produce specific psychological disorders.

Disorders often accompany one another (Jacobson & Newman, 2017; Plana-Ripoll et al., 2019). People diagnosed with one disorder, such as major depressive disorder, are at higher risk for being diagnosed with another, such as an anxiety disorder. Such *comorbidity* results from several factors, such as having overlapping genes that predispose different disorders (Brainstorm Consortium, 2018; Tylee et al., 2022). In one U.S. national sample, 51 percent of people with one disorder were also diagnosed with at least one other disorder (Barr et al., 2022). Comorbidity is common.

Emma McIntyre/Getty Images

Making a scene Actor Constance Wu has achieved acclaim for her roles in the television sitcom *Fresh Off the Boat* and the movies *Crazy Rich Asians* and *Hustlers*. She has also experienced mental health problems, which led her to attempt suicide. “Asian Americans don’t talk about mental health enough,” she said. “While we’re quick to celebrate representation wins, there’s a lot of

avoidance around the more uncomfortable issues within our community" (Kim, 2022). In her memoir *Making a Scene,* she portrays how sexism and racism in Hollywood harm Asian American women's mental health (Wu, 2019).

RP-3 What is the biopsychosocial approach, and why is it important in our understanding of psychological disorders?

ANSWERS IN APPENDIX E

Classifying Disorders—and Labeling People

LOQ 48-3

How and why do clinicians classify psychological disorders, and why do some psychologists criticize diagnostic labels?

In biology, classification creates order. To classify an animal as a "mammal" says a great deal—that it is likely warm-blooded, has hair or fur, and produces milk to nourish its young. In psychiatry and psychology, too, classification aims to order and describe symptoms.

To classify a person's disorder as "schizophrenia" suggests that the person talks incoherently, has irrational beliefs, shows either little emotion or inappropriate emotion, or is completely withdrawn. "Schizophrenia" is a quick way to describe a complex disorder.

Moreover, diagnostic classification gives more than a thumbnail sketch of a disorder. In psychiatry and psychology, classification also aims to *predict* a disorder's future course, *suggest* appropriate treatment, and *guide* research into its causes. To study a disorder, we must first name and describe it.

"I'm always like this, and my family was wondering if you could prescribe a mild depressant."

In many countries, the most common tool for describing disorders is the American Psychiatric Association's *Diagnostic and Statistical Manual of Mental Disorders,* released in 2022 as an updated Text Revision of the fifth edition (**DSM-5-TR**).[2] Physicians and mental health workers use the detailed DSM-5-TR to guide diagnoses and treatment. The DSM-5-TR represents a *categorical* approach (symptoms are present or absent). For example, someone who meets

all of the criteria in TABLE 48.1 may be diagnosed with *insomnia disorder.* Other disorders, such as *posttraumatic stress disorder* and major depressive disorder require people to meet only a certain number of criteria to be diagnosed. The DSM-5-TR includes diagnostic codes from the World Health Organization's *International Classification of Diseases* (ICD), which makes it easy to track worldwide trends in psychological disorders.

TABLE 48.1 Insomnia Disorder

• Feeling unsatisfied with amount or quality of sleep (trouble falling asleep, staying asleep, or returning to sleep)
• Sleep disruption causes distress or diminished everyday functioning
• Happens three or more nights each week
• Occurs during at least three consecutive months
• Happens even with sufficient sleep opportunities
• Independent from other sleep disorders (such as narcolepsy)
• Independent from substance use or abuse
• Independent from other mental disorders or medical conditions
Information from: American Psychiatric Association (2022).

In real-world tests *(field trials)* assessing the DSM-5 categories' reliability, some diagnoses fared well and others fared poorly (Freedman et al., 2013). Clinician agreement on adult posttraumatic

stress disorder and childhood *autism spectrum disorder,* for example, was near 70 percent. (If one psychiatrist or psychologist diagnosed someone with one of these disorders, there was a 70 percent chance that another mental health worker would independently give the same diagnosis.) But for *antisocial personality disorder* and *generalized anxiety disorder,* agreement was closer to 20 percent.

Critics have long faulted the DSM for casting too wide a net and bringing "almost any kind of behavior within the compass of psychiatry" (Eysenck et al., 1983). Some worried that the DSM-5's (2013) even wider net would extend the pathologizing of everyday behavior. For example, the DSM-5 classified severe grief following the death of a loved one as a possible *depressive disorder.* Critics wondered whether such grief—which one grieving person described as "not a problem to be solved, but a process to be lived through"—might instead be considered a common human reaction to tragic life events (Perry, 2022). The DSM-5-TR (2022) responded to this concern with the newly classified *prolonged grief disorder,* diagnosed only when bereavement-related grief lasts more than a year (or 6 months for children and adolescents) and disrupts daily life. Yet grief varies in duration—for some 3 months, for some a year, and for some, a lifetime. "There is no uniform expiration date on normal grief," argue Joanne Cacciatore and Allen Francis (2022). "Pathologizing grief is an insult to the dignity of loving relationships."

A newer *dimensional* approach to classification (in which symptoms are present along a continuum) that builds on the DSM is the U.S.

National Institute of Mental Health's Research Domain Criteria (RDoC) project (Cuthbert, 2022; NIMH, 2022). This dimensional approach argues that mental health problems are a common part of day-to-day life and that people who have one symptom of a disorder are just as worthy of receiving treatment as those who have all of a disorder's symptoms. The RDoC framework fosters "new research approaches that will lead to better diagnosis, prevention, intervention, and cures" (NIMH, 2022). Clinical psychologists, for example, may explore how neural, genetic, and childhood trauma factors influence the development of mental disorders (Damme et al., 2022; Li et al., 2022; Tiecher et al., 2022). Other dimensional approaches, such as the Hierarchical Taxonomy of Psychopathology (HiTOP), recognize different numbers of symptoms and the connections between disorders (Kotov et al., 2017).

Other critics of classification register a more basic complaint—that diagnostic labels, whether categorical or dimensional, can be subjective or even value judgments masquerading as science. Once we label a person, we view that person differently. Labels can change reality by putting us on alert for evidence that confirms our view. If we hear that a new co-worker is mean-spirited, we may treat them suspiciously. They may, in turn, react to us as a mean-spirited person would. Ditto if we're led to believe that someone is smart. Teachers who were told certain students were "gifted" then acted in ways that elicited the behaviors they expected (Snyder, 1984). Labels can be self-fulfilling, and if negative, they convey a stigma.

In one study, therapists watched recorded interviews. If told the interviewees were job applicants, the therapists perceived the interviewees as typical people (Langer & Abelson, 1974; Langer & Imber, 1980). Other therapists who were told they were watching cancer or psychiatric patients perceived the same interviewees as "different from most people." Therapists who thought they were watching an interview of a psychiatric patient perceived him as "frightened of his own aggressive impulses," a "passive, dependent type," and so forth. People, especially in high-income countries, tend to stigmatize those with psychological disorders (Wüsten & Lincoln, 2022). Increasing mental health education, and promoting contact between those who have psychological disorders and those who do not, can reduce this stigma (Corrigan et al., 2012, 2014).

> **"Portray [people with mental illness] sympathetically, and portray them in all the richness and depth of their experience as people, and not as diagnoses."** — American legal scholar and professor Elyn Saks, diagnosed with schizophrenia (TED talk, A Tale of Mental Illness, 2012)

Labels also have power outside the laboratory. Getting a job or finding a place to rent can be a challenge for people recently released from a psychiatric hospital. Label someone as "mentally ill" and people may fear them as potentially violent. That reaction is fading as people increase their understanding of psychological disorders. Public figures have helped foster this understanding by speaking openly about their own struggles with disorders such as anxiety, depression,

and substance abuse—and about how beneficial it was to seek help, receive a diagnosis, and get better through treatment.

So, labels matter. Despite their risks, diagnostic labels have benefits. They help mental health professionals communicate about their cases and study the causes and treatments of disorders. Clients are often relieved to learn that their challenges have a name, and that they are not alone in experiencing their symptoms.

Kevin Mazur/Getty Images

The struggle is real Actor Dwayne "The Rock" Johnson has been vocal about his struggle with depression. "Struggle and pain is real," he said. "I was devastated and depressed" (Parker, 2018). He also "found that, with depression, one of the most important things

you could realize is that you're not alone" (Mosbergen, 2015).

Ask Yourself

Have you or someone you know been diagnosed with a psychological disorder? How do you think a diagnostic label has helped or hurt?

Retrieval Practice

RP-4 What is the value, and what are the dangers, of labeling people with disorders?

ANSWERS IN APPENDIX E

Risk of Harm to Self and Others

People with psychological disorders are more likely to harm themselves than are people without such disorders. Are they also more likely to harm others?

Understanding Suicide

LOQ 48-4

What factors increase the risk of suicide, and what do we know about nonsuicidal self-injury?

Each year some 160,000 Americans are among the drug, alcohol, or suicide "deaths of despair" (Case & Deaton, 2020). Have you ever, in a moment of despair, considered suicide? If so, you have much company. Among the many who entertain the thought, each year some 703,000 despairing people worldwide will complete the act, electing a permanent solution to what might have been a temporary problem (WHO, 2022a). Someone will likely die by suicide in the 40 or so seconds it takes you to read this paragraph.

For those who have been anxious, the risk of suicide is tripled, and for those who have been depressed, the risk is quintupled (Bostwick & Pankratz, 2000; Kanwar et al., 2013). Yet people seldom elect suicide while in the depths of depression, when energy and initiative are lacking. The risk increases when they begin to rebound and become capable of following through (Chu et al., 2016).

> **"But life, being weary of these worldly bars,**
> **Never lacks power to dismiss itself."**
>
> — William Shakespeare, *Julius Caesar,* 1599

Comparing the suicide rates of different groups, researchers have found

- ***national differences:*** Guyana has more than double the suicide rate of the United States, which has double that of Spain (WHO,

2022b). Within Europe, Lithuanians have been five times more likely to die by suicide than Greeks.

- ***racial differences:*** Within the United States, White and Native American people die by suicide roughly twice as often as Black, Hispanic, and Asian people (Curtin & Hedegaard, 2019). The rate among Indigenous Canadians is triple that of other Canadians (Kumar & Tjepkema, 2019).
- ***gender differences:*** Women are much more likely than men to consider or attempt suicide. But worldwide, men are twice as likely to actually die by suicide (ONS, 2019; Ritchie et al., 2019; WHO, 2022b). The methods men use, such as firing a bullet into the head, are more lethal. In the United States, for example, only 13 percent of all suicide attempts end in death—but for those using firearms, that number mushrooms to 90 percent (Juskalian, 2019).
- ***trait differences:*** Suicidal thoughts increase when perfectionists feel driven to reach a goal or standard—to become thin or straight or rich—and find it unattainable (Chatard & Selimbegović, 2011; Smith et al., 2018).
- ***age differences:*** In late adulthood, rates increase worldwide, with the highest rate among those over age 70 (Ritchie et al., 2019).
- ***other group differences:*** Suicide rates have been much higher among the high-income, the nonreligious, and the unmarried (Chen et al., 2020; Norko et al., 2017; VanderWeele et al., 2016, 2017). Gay, transgender, and gender-nonconforming youth who face an unsupportive environment, including family or peer rejection, are also at increased risk of attempting suicide

(Goldfried, 2001; Haas et al., 2011; Hatzenbuehler, 2011; Testa et al., 2017). One in two transgender adults has contemplated suicide, and one in four has attempted suicide (Adams & Vincent, 2019; Yockey et al., 2022).

- ***seasonal differences:*** Suicide rates are highest in April and May, and not (as commonly believed) over the winter holidays (Nock, 2016).
- ***year-by-year differences:*** In most countries, suicide deaths have been decreasing. But in the United States and Canada, suicide deaths have trended upward (FIGURE 48.2). For example, between 2009 and 2019, U.S. high school students' suicide rate increased by 62 percent (CDC, 2019; SAMHSA, 2019). (See the What Drives Us modules for a discussion of social media and teen mental health.)

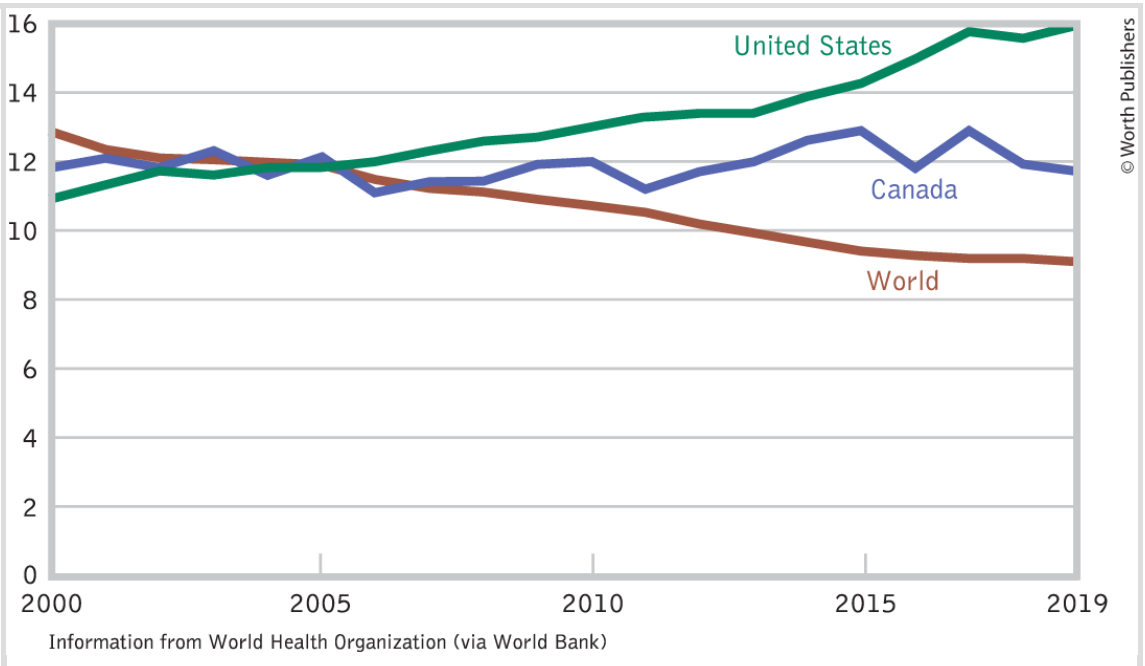

FIGURE 48.2 Suicide death rates, 2000 to 2019 The annual number of suicide deaths per 100,000 people has trended downward worldwide, but upward in the United States

(Ritchie et al., 2022).

Social suggestion may trigger suicidal thinking and behavior. One analysis of 17 million Twitter users' data showed that sharing suicidal thoughts had a ripple effect, spreading suicidal thinking through one's social network (Cero & Witte, 2020). Following highly publicized suicides and TV programs featuring suicide, rates of suicide sometimes increase (Niederkrotenthaler et al., 2019). Sometimes, suicide reverberates throughout a family tree. One 36-year Danish study tracked suicides among 4.4 million people between 1980 and 2016 (Ranning et al., 2022). People were 3.2 times more likely to die by suicide if exposed to a parent's suicide.

Suicide is rarely an act of hostility or revenge. People—especially older adults—may choose death as an alternative to current or future suffering, a way to switch off unendurable pain or relieve a perceived burden on family members. Suicidal urges typically arise when people feel like they don't belong or are a burden to others, when they feel demoralized, or when they are unable to experience joy (Chu et al., 2018; Costanza et al., 2022). Three examples of difficult life circumstances increasing suicide risk:

- The Covid-19 pandemic brought widespread unemployment and social isolation, and a tripling of suicidal thinking (CDC, 2020).
- Following the January 6, 2021, attack on the U.S. Capitol, four of its police officers died by suicide.

- In Britain, 35 percent of women attempting suicide had experienced intimate partner violence in the past year (McManus et al., 2022).

> **"People desire death when two fundamental needs are frustrated to the point of extinction: The need to belong with or connect to others, and the need to feel effective with or to influence others."** — Thomas Joiner (2006, p. 47)

In hindsight, families and friends may recall signs they believe should have forewarned them—verbal hints, giving possessions away, a sudden mood change, or withdrawal and preoccupation with death (Bagge et al., 2017). To judge from surveys of 84,850 people across 17 nations, about 9 percent of people at some point in their lives contemplate suicide. About 3 in 10 of those who think about it will actually attempt suicide; of those, fewer than 1 in 20 will die by suicide (Han et al., 2016; Nock et al., 2008; WHO, 2020).

MARIO ANZUONI/REUTERS/Alamy Stock Photo

Suicide prevention Rapper Lil Nas X was the Trevor Project's 2021 Suicide Prevention Advocate of the Year. The Trevor Project,

which works to prevent suicide and crisis among LGBTQ young people, cited Lil Nas X's mental health advocacy and openness about his sexual orientation and suicidal ideation.

Suicide is difficult to predict. Over the past 50 years, researchers have conducted hundreds of studies examining suicide risk factors, which have yielded little conclusive evidence on whether a person will die by suicide (Knipe et al., 2022). Today's researchers continue to try to solve the suicide puzzle with newer methods and technologies. Using an app that harvests phone data, investigative teams have gained clues to suicide risk by studying teen volunteers' tone of voice, language, photos, music choice, sleep disturbances, and angry words in text messages (Glenn et al., 2020; Servick, 2019). Other researchers are seeking to identify *epigenetic* marks that predict suicide death (Punzi et al., 2022). And still other research teams are developing suicide-predicting AI (artificial intelligence) algorithms using psychological assessments, health records, or social media posts (Ribeiro et al., 2019; Simon et al., 2018; Walsh et al., 2017).

About 46,000 Americans a year die by suicide, half using guns (CDC, 2022). (Poison and drug overdoses account for about 80 percent of suicide *attempts,* but only 14 percent of suicide fatalities.) U.S. states with high gun ownership are states with high suicide rates, even after controlling for poverty and urbanization (Siegel & Rothman, 2016). After Missouri repealed its tough handgun law, its suicide rate went up 15 percent; when Connecticut enacted such a law, its suicide rate dropped 16 percent (Crifasi et al., 2015). Thus, although U.S. gun

owners often keep a gun to feel safer, having a gun in the home makes one less safe, because it substantially *increases* the odds of a family member dying by suicide or homicide (Miller et al., 2022; VPC, 2015; Vyse, 2016).

How can we be helpful to someone who is talking about suicide—who says, for example, "I wish I could just end it all" or "I hate my life; I can't go on"? If people write such things online, you can anonymously contact various social media safety teams (including on Facebook, Twitter, Instagram, YouTube, and Snapchat). If a classmate, friend, or family member talks about suicide, you can

1. ***listen,*** empathize, and offer hope;
2. ***connect*** the person with their campus counseling center; with (in the United States) the 988 Suicide & Crisis Lifeline (by dialing 988) or Crisis Text Line (by texting HOME to 741741); or with support services in other countries (such as CrisisServicesCanada.ca); and
3. ***protect*** someone who appears at immediate risk by seeking help from your campus health or counseling service, a doctor, the nearest hospital emergency room, or 911. Better to disclose a secret than to attend a funeral. Remain connected—online or in person—until the person gets the help they need.

By synthesizing the available evidence, experts have outlined a variety of strategies for community-based suicide prevention (**TABLE 48.2**). Developing and implementing policies and programs based on these strategies—involving the cooperation of educators, health care providers, government officials, and community activists—aims to

enhance individual and community resilience, reducing suicide risk for all.

TABLE 48.2 Community-Based Suicide Prevention Strategies

Strategy	Example
Build economic security	Make sure people have enough money to meet their basic needs (food, shelter), such as by offering job skills training or public housing.
Ensure access to mental health care providers	Lobby health insurance companies to cover mental health conditions. Create programs in communities to ensure enough money to hire mental health care providers.
Create safe environments	Reduce access to firearms among people at risk of suicide. Create community policies to reduce excessive alcohol use.
Promote social connections	Promote programs that bring people together and foster a connection to the local community.
Teach coping and problem-solving skills	Offer free programs teaching parenting skills and relationship strategies.
Identify and support people at risk	Train people to identify warning signs of suicide risk in others and get them the help they need.
Prevent future risk	Encourage those at risk to regularly check in with mental health care providers.

Information from: Stone et al., 2017

Nonsuicidal Self-Injury

Self-harm takes many forms. Some people—mostly adolescents and females—engage in *nonsuicidal self-injury (NSSI)* (Mercado et al., 2017) (FIGURE 48.3). They may, for example, cut or burn their skin, hit themselves, or insert objects under their nails or skin.

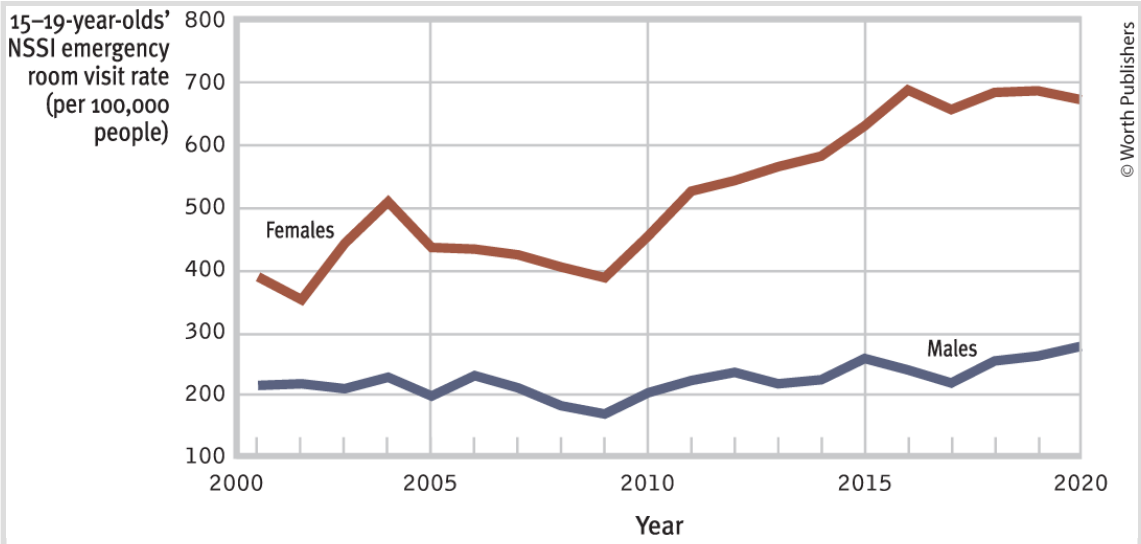

FIGURE48.3 Rates of U.S. nonsuicidal self-injury emergency room visits Self-injury rates peak higher for 15- to 19-year-old females than for same-age males (Mercado et al., 2017). Other countries, including Canada and England, have simultaneously experienced the same gender difference and upward trend (Ritchie et al., 2022).

Those who engage in NSSI often have experienced harassment, stress, or bullying (either as the target of bullies, or as bullies themselves) (Miller et al., 2019; Nesi et al., 2021). They are generally less able to tolerate and regulate emotional distress (Hamza et al., 2015). They are

often both self-critical and impulsive (Beachaine et al., 2019; Cassels et al., 2020).

NSSI is often self-reinforcing (Cummings et al., 2021). People who engage in NSSI may

- find relief from intense negative thoughts through the distraction of pain.
- attract attention and possibly get help.
- relieve guilt by punishing themselves.
- get others to change their negative behavior (bullying, criticism).
- fit in with a peer group.

Does NSSI lead to suicide? Usually not. Those who engage in NSSI are typically suicide gesturers, not suicide attempters (Liu et al., 2022; Nock & Kessler, 2006). Nevertheless, NSSI is a risk factor for suicidal thoughts and future suicide attempts, especially when co-existing with a bipolar disorder (Geulayov et al., 2019). If people do not find help, their nonsuicidal behavior may escalate to suicidal thoughts and, finally, to suicide attempts. Thankfully, various forms of psychotherapy can benefit people who engage in NSSI (Prada et al., 2018; Turner et al., 2014).

Does Disorder Equal Danger?

LOQ 48-5

Do psychological disorders predict violent behavior?

September 16, 2013, started like any other Monday at the Navy Yard in Washington, DC, with people arriving early to begin work. Then government contractor Aaron Alexis entered the building and began shooting. An hour later, 13 people were dead—including Alexis, who had a history of mental illness and had earlier written that an "ultra low frequency attack is what I've been subject to for the last three months. And to be perfectly honest, that is what has driven me to this."

This mass shooting, like many others since, reinforced public perceptions that people with psychological disorders pose a threat (Barry et al., 2013; Jorm et al., 2012). "People with mental illness are getting guns and committing these mass shootings," said U.S. Speaker of the House Paul Ryan (2015). In one survey, 84 percent of Americans agreed that "increased government spending on mental health screening and treatment" would be a "somewhat" or "very" effective "approach to preventing mass shootings at schools" (Newport, 2012). "Anybody who shoots somebody else has a mental health challenge," said Texas Governor Greg Abbott in the aftermath of the 2022 Uvalde, Texas, school massacre (Hixenbaugh & Siemaszko, 2022).

Can clinicians indeed foretell who is likely to do harm? *No.* Most violent criminals and mass murderers are not mentally ill, and most mentally ill people are not violent (Brucato et al., 2021; Whiting et al., 2021). Moreover, clinical prediction of violence is unreliable. The few people with disorders who commit violent acts tend to be either those, like the Navy Yard shooter, who experience threatening delusions and

hallucinated voices that command them to act, or those who abuse substances (Douglas et al., 2009; Elbogen et al., 2016; Fazel et al., 2009, 2010).

Top: Eric Gay/AP Photo; bottom: Marco Bello/REUTERS/Alamy Stock Photo

Mental health and mass shootings Following mass shootings such as the 2022 Uvalde, Texas, slaughter of 19 schoolchildren and 2 adults, people wondered: Could mental health workers identify people who are violence-prone and remove their right to gun ownership? Not likely. Most homicide "is committed by healthy people in the grip of everyday emotions using guns" (Friedman, 2017).

People with disorders are more likely to be *victims* than perpetrators of violence (Buchanan et al., 2019). According to the U.S. Surgeon General's Office (1999, p. 7), "there is very little risk of violence or harm to a stranger from casual contact with an individual who has a mental disorder." Better predictors of violence are alcohol or drug use, previous violence, gun availability, and—as in the case of the repeatedly head-injured and ultimately homicidal National Football League player Aaron Hernandez—brain damage (Belson, 2017). Mass-killing shooters have one more thing in common: They are mostly young males.

Ask Yourself

Why do you think people often believe those with psychological disorders are dangerous?

RP-6 Those with psychological disorders are more likely to be victims of violence rather than perpetrators of violence. True or false?

ANSWERS IN APPENDIX E

Rates of Psychological Disorders

LOQ 48-6

How many people have, or have had, a psychological disorder? What are some of the risk factors?

Who is most vulnerable to psychological disorders? At what times of life? To answer such questions, many countries have conducted lengthy structured interviews with their citizens. After asking hundreds of questions that probed for symptoms (for example, "Has there ever been a period of two weeks or more when you felt like you wanted to die?"), researchers have estimated the current, prior-year, and lifetime prevalence of various disorders. (See **TABLE 48.3**.)

TABLE 48.3 Percentage in the U.S. Reporting Selected Psychological Disorders "in the Past Year"

Psychological Disorder	Percentage
Phobia of specific object or situation	9.1
Major depressive disorder	7.8
Social anxiety disorder	7.1
Attention-deficit/hyperactivity disorder (ADHD)	4.4
Posttraumatic stress disorder (PTSD)	3.6
Bipolar disorders	2.8

Generalized anxiety disorder	2.7
Obsessive-compulsive disorder (OCD)	1.2
Schizophrenia	< 0.5
Data from: National Institute of Mental Health (2018).	

Do rates of psychological disorder vary by place? The Global Burden of Disease Study estimated the prevalence of mental disorders in 204 countries and territories (GBD, 2022; **FIGURE 48.4**). Cultures vary. For example, the highest rates of eating disorders are in high-income Monaco and Australia, and the lowest rates in low-income Somalia.

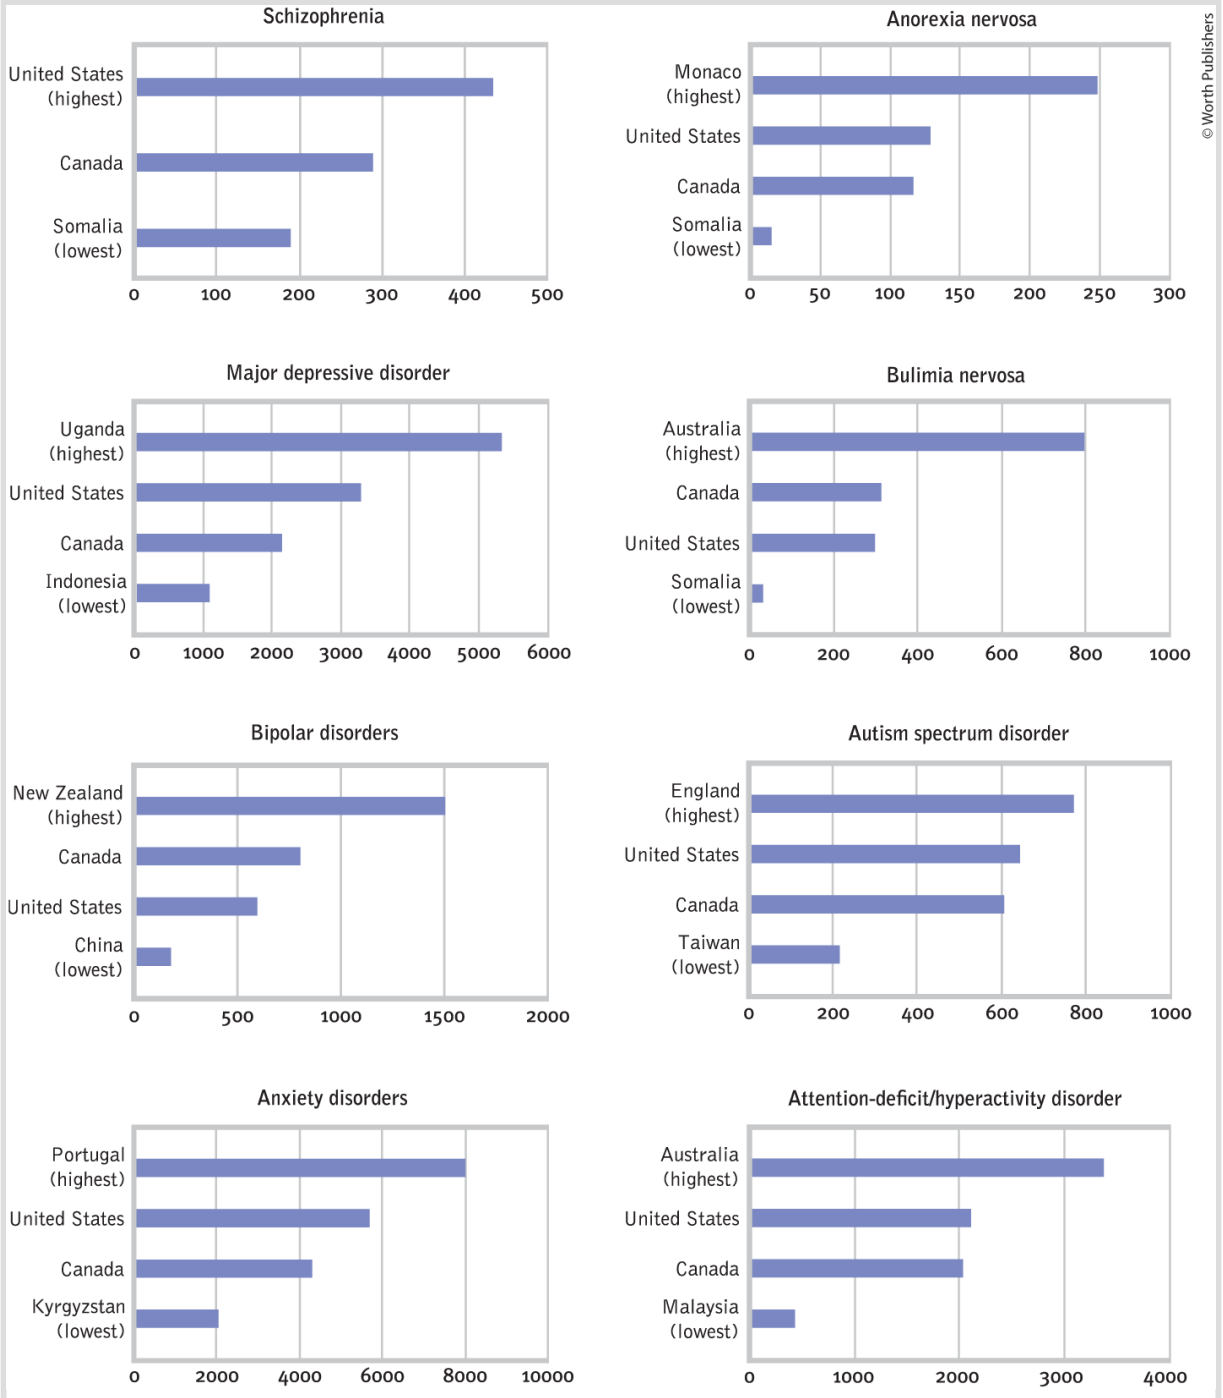

FIGURE 48.4 Highest and lowest rates of selected disorders worldwide These data, from an investigation of 204 countries and territories, show the number of cases per 100,000 people (controlling for age). The United States and Canada are shown for comparison. (Data from GBD, 2022.)

Moreover, immigrants to the United States from Mexico, Africa, and Asia averaged better mental health than their U.S.-born counterparts with the same ethnic heritage (Breslau et al., 2007; Maldonado-Molina et al., 2011). For example, compared with Mexican Americans born in the United States, Mexican Americans who have recently immigrated are less at risk for mental disorders—a phenomenon known as the *immigrant paradox* (Salas-Wright et al., 2018).

What increases vulnerability to mental disorders? As **TABLE 48.4** indicates, there are various risk and protective factors for mental disorders. One predictor—poverty—crosses ethnic and gender lines. The incidence of serious psychological disorders is 2.5 times higher among those below the poverty line (CDC, 2014). This poverty-disorder correlation raises further questions: Does poverty cause disorders? Or do disorders cause poverty? The answer varies with the disorder. Schizophrenia understandably leads to poverty. Yet poverty can cause distress that increases the risk of certain disorders. A recession-related financial, job, or housing loss may produce lingering depression and anxiety (Forbes & Krueger, 2019).

TABLE 48.4 Risk and Protective Factors for Mental Disorders

Level	Risk factors	Protective factors
Individual attributes	Low self-esteem	Self-esteem, confidence
	Cognitive/emotional immaturity	Ability to solve problems and manage stress or adversity

	Difficulties in communicating	Communication skills
	Medical illness, substance use	Physical health, fitness
Social circumstances	Loneliness, bereavement	Social support of family and friends
	Neglect, family conflict	Good parenting/positive family interaction
	Exposure to violence/abuse	Physical security and safety
	Low income and poverty	Economic security
	Difficulties or failure at school	Scholastic achievement
	Work stress, unemployment	Satisfaction and success at work
Environmental factors	Poor access to basic services	Equality of access to basic services
	Injustice and discrimination	Social justice, tolerance, integration
	Social and gender inequalities	Social and gender equality
	Exposure to war or disaster	Physical security and safety
Information from WHO, 2012.		

As economic development enabled a dramatic poverty-rate reduction for the North Carolina Eastern Band of Cherokee Indians, researchers saw the opportunity for a natural experiment that could investigate the poverty-pathology link. They tracked the community's rates of children's behavior problems over time. When the study began, children of poverty exhibited more deviant and aggressive behaviors. After 4 years, children whose families had moved above the poverty line exhibited a 40 percent decrease in behavior problems. But children whose families remained in poverty or were never in poverty exhibited no change (Costello et al., 2003).

At what times of life do disorders strike? About half of people with a disorder experience their first symptoms by the mid-teens, and three-quarters do so by the mid-twenties (Kessler et al., 2007; Robins & Regier, 1991). Among the earliest to appear are the symptoms of antisocial personality disorder (median age 8) and of phobias (median age 10). Alcohol use disorder, obsessive-compulsive disorder, bipolar disorders, and schizophrenia symptoms appear at a median age near 20. Major depressive disorder often hits somewhat later, at a median age of 25.

epigenetics
DSM-5-TR

Module Test

Test Yourself Answer the following questions on your own first, then "show" the answers here, or check your answers in Appendix E.

1. Two major disorders that are found worldwide are schizophrenia and _____ _____ _____.

2. Robert is embarrassed that it takes him several minutes to parallel park his car. He usually gets out of the car once or twice to inspect his distance, both from the curb and from

the nearby cars. Should he worry about having a psychological disorder?

3. A therapist says that psychological disorders are illnesses, and people with these disorders should be treated as patients in a hospital. This therapist's belief reflects the _____ model.

4. What is an example of a culturally related psychological disorder?

5. Many psychologists reject the disorder-as-illness view and instead contend that other factors may also be involved—for example, the person's level of stress and ways of coping. This view represents the _____ approach.
   a. medical
   b. epigenetics
   c. biopsychosocial
   d. diagnostic

6. Why is the DSM, and the DSM-5 in particular, considered controversial?

7. _____ (Women/Men) are more likely than _____ (women/men) to die by suicide.

8. The symptoms of _____ appear around age 10; _____ tend[s] to appear later, around age 25.
   a. schizophrenia; bipolar disorders

b. bipolar disorders; schizophrenia
c. major depressive disorder; phobias
d. phobias; major depressive disorder

MODULE 49: Anxiety Disorders, Obsessive-Compulsive and Related Disorders, Trauma- and Stressor-Related Disorders, and Somatic Symptom and Related Disorders

Anxiety is part of life. Speaking in front of a class, peering down from a ladder, or waiting to learn the results of a final exam can make any of us feel anxious.

Anxiety can both help us and hurt us. Anxiety, it has been said, keeps us alive while also diminishing our living. A little anxiety prompts action and keeps us safe, but persistent anxiety can overwhelm and paralyze us. It may cause us to avoid talking or making eye contact —"shyness," we call it. Fortunately for most people, this uneasiness is neither intense nor persistent.

Some people, however, are especially prone to fearing the unknown and noticing and remembering perceived threats—as if living while horror-movie background music plays (Gorka et al., 2017; Mitte, 2008). When the brain's danger-detection system becomes hyperactive—with fearsome pop-up thoughts—we are at greater risk for an *anxiety disorder* and three other disorders involving anxiety: *obsessive-*

compulsive disorder (OCD), posttraumatic stress disorder (PTSD), and the *somatic symptom disorders.*

Anxiety Disorders

LOQ 49-1

How do generalized anxiety disorder, panic disorder, and specific phobias differ?

The **anxiety disorders** are marked by distressing, persistent anxiety or by dysfunctional anxiety-reducing behaviors. For example, people with **social anxiety disorder** become extremely anxious in social settings where others might judge them, such as parties, class presentations, or even eating in public. People with social anxiety may experience palpitations, tremors, blushing, and sweating when giving a presentation, taking an exam, or meeting an authority figure, fearing embarrassment or rejection. By avoiding eye contact or staying home, they can temporarily avoid anxious feelings. But in the long run, such strategies are maladaptive: Avoiding others prevents them from learning to cope and leaves them feeling lonely (Günther et al., 2021; Oren-Yagoda et al., 2022; Rapee et al., 2022).

Let's take a closer look at three other anxiety disorders:

- ***generalized anxiety disorder,*** in which a person, for no apparent reason, worries about many different things they cannot control and is continually tense and uneasy;

- ***panic disorder,*** in which a person experiences one or more *panic attacks*—sudden episodes of intense dread and "fight or flight" arousal—and fears a future panic attack; and
- ***specific phobias,*** in which a person is intensely and excessively afraid of a specific object, activity, or place.

Generalized Anxiety Disorder

For two years, Tom, a 27-year-old electrician, was bothered by dizziness, sweating palms, and heart palpitations. He felt on edge and sometimes found himself shaking. Tom mostly hid his symptoms from his family and co-workers. But he allowed himself few other social contacts, and occasionally he felt so anxious he would leave work. Neither his family doctor nor a neurologist could find any physical problem.

Tom's experiences suggest **generalized anxiety disorder**, which is marked by excessive and uncontrollable worry that persists for 6 months or more. People with this condition (two-thirds are women) worry continually, and they are often jittery, agitated, and sleep-deprived (McLean & Anderson, 2009). Their *autonomic nervous system* arousal may leak out through furrowed brows, twitching eyelids, trembling, perspiration, or fidgeting. Concentration suffers, as everyday worries demand continual attention. Emotions can feel overwhelming, confusing, and hard to manage (Mennin et al., 2005).

Those affected usually cannot identify, relieve, or avoid their anxiety. To use Sigmund Freud's term, the anxiety is *free-floating* (not linked to a specific stressor or threat). Generalized anxiety disorder often co-occurs with a depressed mood. But even without depression, generalized anxiety disorder tends to be disabling. Moreover, it may lead to physical problems, such as high blood pressure. As time passes, however, emotions tend to mellow, and by age 50, generalized anxiety disorder becomes relatively rare (Rubio & López-Ibor, 2007).

Panic Disorder

Some people experience intense anxiety that escalates into a terrifying panic attack—a several-minutes-long episode of intense fear that something horrible is about to happen. The body's fight-or-flight system goes into overdrive: Irregular heartbeat, chest pains, shortness of breath, choking, trembling, or dizziness may accompany the panic. One woman recalled suddenly feeling

> hot and as though I couldn't breathe. My heart was racing and I started to sweat and tremble and I was sure I was going to faint. Then my fingers started to feel numb and tingly and things seemed unreal. It was so bad I wondered if I was dying and asked my husband to take me to the emergency room. By the time we got there (about 10 minutes) the worst of the attack was over and I just felt washed out (Greist et al., 1986).

© Walt Disney Pictures/Entertainment Pictures/Alamy Stock Photo

Understanding panic At age 7, actor Emma Stone started having panic attacks. While playing at a friend's house, she became convinced that the house was on fire. "There was nothing in me that didn't think we were going to die," she said (Gonzalez, 2018). Therapy and meditation have helped Stone cope with her anxiety. Today, she says, publicly discussing her anxiety helps her "own it and realize that this is something that is part of me but it's not who I am."

For the 3 percent of people with **panic disorder**, panic attacks recur. These anxiety tornados strike suddenly, wreak havoc, and disappear, but are not forgotten. Ironically, worries about anxiety—perhaps fearing another panic attack, or fearing anxiety-related symptoms in public—can amplify anxiety symptoms (Olatunji & Wolitzky-Taylor, 2009). After several panic attacks, people may avoid situations where panic might strike (**FIGURE 49.1**). People with panic disorder are two to three times more likely than the general population to think about or attempt suicide (Zhang et al., 2022).

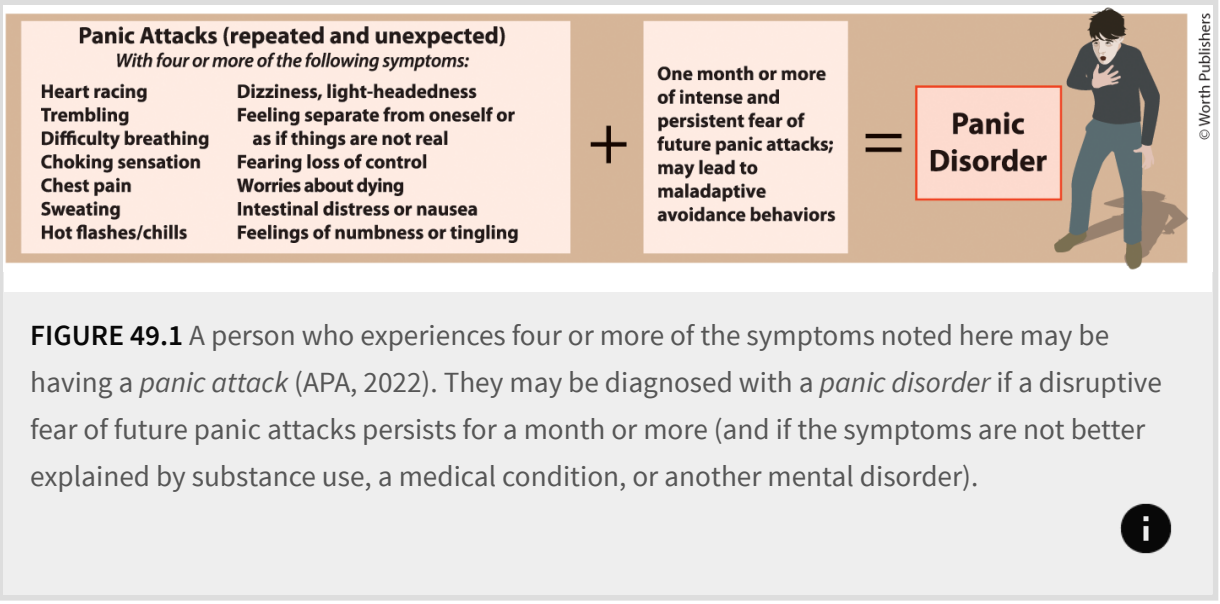

FIGURE 49.1 A person who experiences four or more of the symptoms noted here may be having a *panic attack* (APA, 2022). They may be diagnosed with a *panic disorder* if a disruptive fear of future panic attacks persists for a month or more (and if the symptoms are not better explained by substance use, a medical condition, or another mental disorder).

If their fear is intense enough, people with panic disorder may also develop *agoraphobia*—fear or avoidance of public situations from which escape might be difficult. People with agoraphobia may avoid being outside the home, in a crowd, or at a coffee shop or grocery store. Smokers have at least a doubled risk of panic disorder and greater symptoms when they do have an attack (Knuts et al., 2010; Zvolensky & Bernstein, 2005). Because nicotine is a stimulant, lighting up doesn't lighten us up.

Charles Darwin began experiencing panic disorder at age 28, after spending 5 years sailing the world. He moved to the country, avoided social gatherings, and traveled only in his wife's company. But the relative seclusion did free him to elaborate his evolutionary theory. "Even ill health," he reflected, "has saved me from the distraction of society and its amusements" (quoted in Ma, 1997).

Specific Phobias

We all live with some fears. But people with **specific phobias** are consumed by a persistent, excessive fear and avoidance of some object, activity, or place—for example, animals, insects, heights, blood, or enclosed spaces (FIGURE 49.2). Many people avoid the triggers (such as high places) that arouse their fear, and they manage to live with their phobia. Others are incapacitated. Marilyn, an otherwise healthy and happy 28-year-old, feared thunderstorms so much that she felt anxious as soon as a weather forecaster mentioned possible storms later in the week. If her husband was away when a storm was forecast, she often stayed with a close relative. During a storm, she hid from windows and buried her head to avoid seeing the lightning.

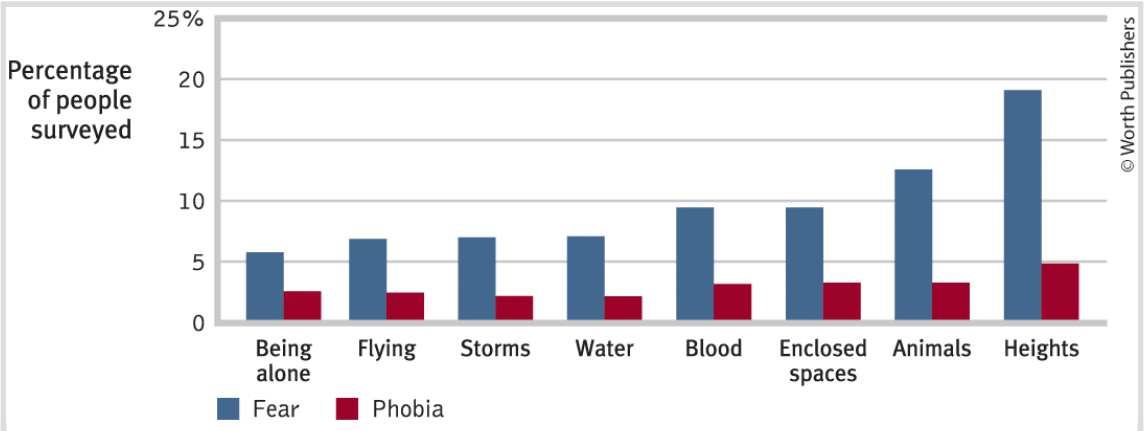

FIGURE 49.2 Some common specific fears Researchers surveyed Dutch people to identify the most common events or objects they feared. An intense fear becomes a specific phobia if it provokes a compelling, irrational desire to avoid the dreaded object or situation. (Data from Depla et al., 2008.)

Retrieval Practice

RP-1 Unfocused tension, apprehension, and arousal are symptoms of _____ _____ disorder.

RP-2 Those who experience unpredictable periods of terror and intense dread, accompanied by frightening physical sensations, may be diagnosed with _____ disorder.

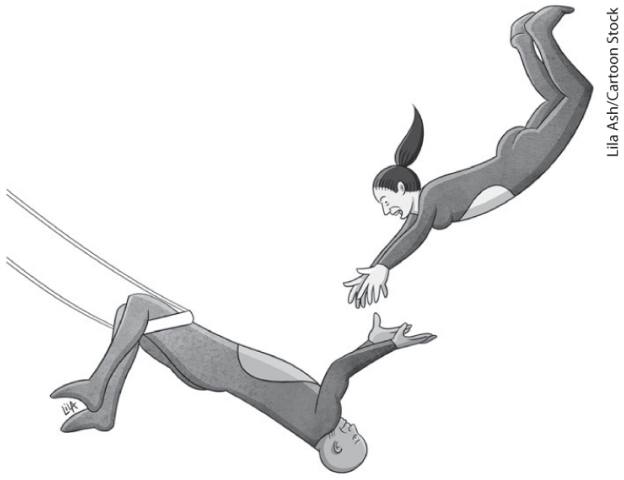
RP-3 If a person is focusing anxiety on specific feared objects, activities, or situations, that person may have a _____ _____.

ANSWERS IN APPENDIX E

Obsessive-Compulsive and Related Disorders

LOQ 49-2

What is *OCD?*



Obsessive-compulsive and related disorders are characterized by the presence of obsessions and compulsions. *Obsessive thoughts* are unwanted, intrusive, and persistent. *Compulsive behaviors* are responses to those thoughts. As with the anxiety disorders, we can see aspects of **obsessive-compulsive disorder (OCD)** in our everyday behavior.

We are all at times obsessed with thoughts, and we may behave compulsively. Have you ever felt a bit anxious about how your living space will appear to others and found yourself checking and cleaning one last time before your guests arrived? Or, perhaps worried about an upcoming exam, you caught yourself lining up your study materials "just so" before studying? Our everyday lives are full of little rehearsals and fussy behaviors. They cross the fine line between "typical" and "disordered" only when they *persistently interfere* with everyday living and cause distress. Checking that you locked the door is typical; checking 10 times is not. (TABLE 49.1 offers more examples.) At some time during their lives, often during their late teens or early adulthood, about 2 percent of people cross that line from typical preoccupations and fussiness to debilitating disorder (Kessler et al., 2012). Although people know their anxiety-fueled obsessive thoughts are irrational, the thoughts can become so haunting, and the compulsive rituals so intensely time-consuming, that effective functioning—including healthy sleep and school success—becomes nearly impossible (Pérez-Vigil et al., 2018; Segal & Carmona, 2022).

TABLE 49.1 Common Obsessions and Compulsions Among Children and Adolescents With Obsessive-Compulsive Disorder

	Thought or Behavior	Percentage Reporting Symptom

Obsessions (repetitive *thoughts*)	Concern with dirt, germs, or toxins	40
	Something terrible happening (fire, death, illness)	24
	Symmetry, order, or exactness	17
Compulsions (repetitive *behaviors*)	Excessive hand washing, bathing, toothbrushing, or grooming	85
	Repeating rituals (in/out of a door, up/down from a chair)	51

"Wait—did you wash your hands?"

OCD is more common among teens and young adults than among older people (Samuels & Nestadt, 1997). A 40-year follow-up study of 144 Swedes diagnosed with the disorder found that, for most, the

obsessions and compulsions had gradually lessened, though only 1 in 5 had completely recovered (Skoog & Skoog, 1999).

Kelly Sullivan/Getty Images

Writing with OCD Author John Green's personal experience with obsessive-compulsive disorder informed his novel, *Turtles All the Way Down* (Flood, 2017). Green explained: "It's like there is an invasive weed that just spreads out of control. It starts out with one little thought and then slowly that becomes the only thought that you're able to have, the thought that you're … trying desperately to distract yourself from" (Gross, 2018).

Some people experience other OCD-related disorders, such as *hoarding disorder* (cluttering their space with acquired possessions they can't part with), *body dysmorphic disorder* (preoccupation with perceived body defects; repeatedly checking their appearance in the

mirror), *trichotillomania* (hair-pulling disorder), or *excoriation* (skin-picking) *disorder.* Many people have some clutter in their living space or feel sensitive about their appearance. But for these common behaviors and feelings to be considered an OCD-related disorder, they must occur frequently and disrupt people's lives—their social life, work, or daily functioning.

Trauma- and Stressor-Related Disorders

LOQ 49-3

What is *PTSD?*

While serving overseas, one soldier, Jesse, saw the killing "of children and women. It was just horrible for anyone to experience." Back home, he experienced "real bad flashbacks" (Welch, 2005). Jesse is not alone. In one study of 104,000 veterans returning from Iraq and Afghanistan, 25 percent were diagnosed with a psychological disorder (Seal et al., 2007). The most frequent diagnosis was **posttraumatic stress disorder (PTSD)**, one of the **trauma- and stressor-related disorders**. Survivors of terror, torture, sexual assault, earthquakes, and refugee displacement have also exhibited PTSD (Charlson et al., 2016; Nichter et al., 2022). The hallmark symptoms are recurring vivid, distressing memories and nightmares. PTSD also often entails laser-focused attention on possible threats, social withdrawal, and

jumpy anxiety (Clauss et al., 2022; Fried et al., 2018). To cope with PTSD symptoms, people sometimes engage in harmful alcohol use (Luciano et al., 2022).

Many of us will experience a traumatic event at some point in our lives. Yet most people, after traumatic experiences, display *resiliency* by returning to their baseline of healthy functioning (Galatzer-Levy et al., 2018). During the early months of the Covid pandemic, people's self-reported anxiety and depression rose sharply, and then—displaying human resilience—subsided (Banks et al., 2021; Fancourt et al., 2021).

Although philosopher Friedrich Nietzsche's (1889/1990) idea that "what does not kill me makes me stronger" is not true for all, about half of trauma survivors report *posttraumatic growth*—marked by a greater appreciation for life and its close relationships, more compassion, or increased spirituality and life purpose (X. Wu et al., 2019). The trauma remains a negative, but it can change one's perspective for the better. Sometimes, tears enable triumphs.

Chip Somodevilla/Getty Images

PTSD in Parkland In the 2018 Parkland, Florida, school shooting, Samantha Fuentes (at right) witnessed friends dying, and shrapnel struck her face and legs. She later reported PTSD symptoms, including a fear of returning to the school, and jumping at the sound of a slammed door. Two other student survivors died by suicide in 2019, including one diagnosed with PTSD (Mazzei, 2019).

Why do some 5 to 10 percent of people develop PTSD after a traumatic event while others do not (Bonanno et al., 2011)? Multiple factors, including personality and social support, matter. One important influence is the amount of emotional distress: The higher the distress (such as the level of physical torture suffered by prisoners of war), the greater the risk for posttraumatic symptoms (King et al., 2015; Ozer et al., 2003). In a study of child survivors of the 2020 Beirut port explosion—which killed 200 people and injured 7,000—children who were near the blast (compared to children who were in the region, but far from the site of the catastrophe) had quadruple the risk of a subsequent PTSD diagnosis (Maalouf et al., 2022).

Fadel Itani/NurPhoto/Alamy Stock Photo

Closeness to terror In the 2020 Beirut port explosion (pictured here), the 2001 terrorist attack in New York, and the 2011 massacre at a Norwegian summer camp, the closer survivors were to the heart of the terror, the more likely PTSD became (Bonanno et al., 2006; Glad et al., 2020).

What else influences PTSD development? Individual differences in memory processing matter. In memory testing of people affected by a Paris terror attack, those who experienced PTSD exhibited more difficulty inhibiting unwanted memories than did those not experiencing PTSD (Mary et al., 2020).

Exposure to violence also increases the risk of experiencing PTSD. African American and Puerto Rican people who experienced repeated violent crime, such as being threatened with a weapon or assaulted, also faced a higher-than-average risk of experiencing PTSD (Pahl et al., 2020). Other studies show that 1 in 4 U.S. college women experience sexual assault, and those who were assaulted had a higher-than-average risk of PTSD (AAU, 2020; Dworkin et al., 2017).

Some people may have a more sensitive emotion-processing limbic system that floods their bodies with stress hormones (Duncan et al., 2017; Kosslyn, 2005). Genes and gender also matter. Twins, compared with nontwin siblings, more commonly share PTSD risk factors (Gilbertson et al., 2006). And after a traumatic event, women

experience PTSD more often than do men (Olff et al., 2007; Ozer & Weiss, 2004).

Some psychologists believe that PTSD has been overdiagnosed (Dobbs, 2009; McNally, 2003). Too often, say critics, PTSD gets stretched to include typical stress-related bad memories and dreams. And some well-intentioned procedures—such as "debriefing" people by asking them to revisit the experience and vent their emotions immediately after the traumatic event—may worsen stress reactions (Bonanno et al., 2010; Wakefield & Spitzer, 2002).

Retrieval Practice

RP-4 Those who experience unwanted repetitive thoughts or actions may have _____-_____ disorder.

RP-5 Those with symptoms of recurring memories and nightmares, social withdrawal, jumpy anxiety, numbness of feeling, and/or insomnia for weeks after a traumatic event may be diagnosed with _____ _____ disorder.

ANSWERS IN APPENDIX E

Somatic Symptom and Related

Disorders

LOQ 49-4

What is a *somatic symptom disorder?*

Among the common problems bringing people into doctors' offices are "medically unexplained illnesses" (Johnson, 2008). Earl becomes dizzy and nauseated shortly before he expects his wife home. Neither his primary care physician nor a neurologist can identify a physical cause. They suspect his symptoms have an unconscious psychological origin, possibly triggered by his feelings about his wife. Earl has a **somatic symptom disorder** (formerly known as *somatoform disorder*).

We have all experienced inexplicable physical symptoms under stress. Being told the problem is "all in your head" gives no comfort. Although the symptoms may be psychological in origin, they are genuinely felt. One person may have a variety of complaints—vomiting, dizziness, blurred vision, difficulty swallowing. Another may experience severe and prolonged pain. Such symptoms become a disorder when they are associated with significant distress and impaired functioning.

Cultural context greatly affects people's physical complaints and how they explain them (Kirmayer & Sartorius, 2007). In China, anxiety disorders are the most common psychological disorder (Huang et al., 2019). Yet psychological explanations of anxiety and depression are

socially less acceptable there than in many Western countries, so people less often express the emotional aspects of distress. The Chinese appear more sensitive to—and more willing to report—the physical symptoms of their distress (Ryder et al., 2008).

Somatic symptom and related disorders send people not to a psychologist or psychiatrist but to a physician. This is especially true of those who experience **illness anxiety disorder** (previously called *hypochondriasis*). People with this relatively common disorder interpret normal sensations (a stomach cramp today, a headache tomorrow) as symptoms of a dreaded disease. No amount of reassurance by any physician convinces the patient that the trivial symptoms do not reflect a serious illness. So, the patient moves on to another physician—seeking and receiving more medical attention, but failing to confront the disorder's psychological roots. Other patients with illness anxiety disorder cope with their fears by avoiding medical care.

Ask Yourself

Can you recall (as most people can) times when you have fretted needlessly over a normal bodily sensation?

RP-6 What does *somatic* mean, and how does it apply to a *somatic symptom disorder?*

ANSWERS IN APPENDIX E

Understanding Anxiety Disorders, Obsessive-Compulsive and Related Disorders, Trauma- and Stressor-Related Disorders, and Somatic Symptom and Related Disorders

LOQ 49-5

How do learning, cognition, and biology contribute to the feelings and thoughts that mark anxiety disorders, OCD, PTSD, and somatic symptom disorders?

Anxiety is a feeling. It is also a cognition—a doubt-laden self-evaluation. How do these anxious feelings and thoughts arise? Most psychologists attribute them to learning, cognition, and biology.

Learning

Through *classical conditioning* (see Learning modules), our fear responses can become linked with formerly neutral objects and events. To understand the link between learning and anxiety, researchers have given lab rats unpredictable electric shocks (Schwartz, 1984). The rats were like assault survivors who report

feeling anxious when returning to the scene of the crime: They learned to become uneasy in their lab environment.

Likewise, anxious or traumatized people learn to associate their anxiety with certain cues (Christian & Levinson, 2022). In one survey, 58 percent of those with social anxiety disorder experienced their disorder after a traumatic event (Öst & Hugdahl, 1981). Anxiety or an anxiety-related disorder is more likely to develop when bad events happen unpredictably and uncontrollably (Field, 2006; Mineka & Oehlberg, 2008). Black people residing in the United States and Canada who experience frequent racial discrimination—a type of bad event that is both unpredictable and out of their control—are at greater risk of anxiety (Paradies et al., 2015; Kogan et al., 2022). Even a single painful and frightening event may trigger a full-blown phobia, thanks to classical conditioning's *stimulus generalization* and operant conditioning's *reinforcement.*

Stimulus generalization occurs when a person experiences a fear-provoking event and later develops a fear of similar events. My [DM's] car was once struck by a driver who missed a stop sign. For months afterward, I felt a twinge of unease when any car approached from a side street. Combat veterans exposed to frequent explosions may experience panic attacks and flashbacks at the sound of fireworks.

Reinforcement helps maintain learned fears and anxieties. Anything that enables us to avoid or escape a feared situation can reinforce maladaptive behaviors. Fearing a panic attack, we may decide not to

leave the house. Reinforced by feeling calmer, we are likely to repeat that behavior (Antony et al., 1992). So, too, with compulsive behaviors. If washing our hands relieves our feelings of anxiety, we may rewash our hands when those feelings return.

Cognition

Conditioning influences our feelings of anxiety, but so do our thoughts, memories, interpretations, and expectations. By observing others, we can learn to fear what they fear. Nearly all monkeys raised in the wild fear snakes, but lab-raised monkeys do not. Surely, most wild monkeys do not actually suffer snake bites. Do they learn their fear through observation?

To find out, Susan Mineka (1985, 2002) experimented with six monkeys raised in the wild (all strongly fearful of snakes) and their lab-raised offspring (virtually none of which feared snakes). After repeatedly observing the wild-raised monkeys refuse to reach for food in the presence of a snake, the lab-raised monkeys developed a similar strong fear of snakes that persisted when retested 3 months later. We humans similarly learn fears by observing others (Helsen et al., 2011; Olsson et al., 2007).

Although it pays to be alert to dangers, anxiety is often a response to the “fake news” we produce ourselves. One study that followed people with anxiety disorders found that more than 9 in 10 of their worries proved groundless (LaFreniere & Newman, 2020). Such people tend to

be *hypervigilant*. They more often *interpret* stimuli as threatening (Everaert et al., 2018). A pounding heart signals a heart attack; a lone spider indicates an infestation; an everyday disagreement with a friend spells a doomed relationship. And they more often *remember* threatening events (Van Bockstaele et al., 2014). Anxiety is especially common when people cannot switch off such intrusive thoughts and feel helpless (Franklin & Foa, 2011).

Ask Yourself

What is a fear that you have learned? How were conditioning or cognition involved?

Biology

Conditioning and cognition can't explain all aspects of anxiety disorders, OCD, or trauma-related disorders like PTSD. Our biology also plays a role. Physically stronger people, for example, tend to be less anxious (Kerry & Murray, 2021). And men, who are often physically stronger than women, also tend to live with less self-protective anxiety (Benenson et al., 2021; Courtright et al., 2013).

Genes

Among monkeys, fearfulness runs in families. A monkey reacts more strongly to stress if its close biological relatives are anxiously reactive (Suomi, 1986). So, too, with people. Although twins, in general, are not at higher risk for disorders, if one identical twin has an anxiety

disorder, the other is also at risk (Polderman et al., 2015). Even when raised separately, identical twins may develop similar specific phobias (Carey, 1990; Eckert et al., 1981). One pair of separated identical twins independently became so afraid of water that each would wade into the ocean backward and only up to her knees. Another pair of twins with OCD rarely left their house, took hours-long showers, used five bottles of disinfecting rubbing alcohol daily, and, tragically, died together in an apparent suicide pact (Schmidt, 2018).

Given the genetic contribution to anxiety disorders, researchers are sleuthing the culprit genes. Researchers have identified gene variations associated with typical anxiety disorder symptoms (Purves et al., 2020). Other teams have found genes associated specifically with OCD or PTSD (Girgenti et al., 2021; Lin et al., 2022). But remember that behavior is typically influenced by *many genes each having small effects.* Thus, large-scale research further explores how the whole of our genome predicts anxiety (Smoller, 2020).

Some genes may influence anxiety disorders by regulating brain levels of neurotransmitters. These neurotransmitters include

- *serotonin,* which influences sleep, mood, and attending to threats;
- *glutamate,* which heightens activity in the brain's alarm centers; and
- *GABA,* which inhibits neural activity to produce a calming effect (Pergamin-Hight et al., 2012; Ross et al., 2021; Welch et al., 2007).

So genes matter. Some people have genes that make them like orchids—fragile, yet capable of beauty under favorable circumstances. Others are like dandelions—hardy, and able to thrive in varied circumstances (Ellis & Boyce, 2008; Pluess & Belsky, 2013).

But experience affects gene expression. A history of wartime trauma or child abuse can leave long-term *epigenetic marks.* These molecular tags attach to our chromosomes and turn certain genes on or off. Thus, traumatic experiences can increase the likelihood that a genetic vulnerability to a disorder such as PTSD will be expressed (Wang et al., 2022; Zannas et al., 2015).

The Brain

Our experiences change our brain, paving new pathways. Traumatic fear-learning experiences can leave tracks in the brain, altering fear circuits within the amygdala (Couette et al., 2022; Kredlow et al., 2022). These fear pathways create easy inroads for more fear experiences (Armony et al., 1998).

Social anxiety disorder, generalized anxiety disorder, panic attacks, specific phobias, OCD, and PTSD express themselves biologically as overarousal of brain areas involved in impulse control and habitual behaviors. These disorders reflect the brain's danger-detection system gone hyperactive—producing anxiety when little danger exists. In OCD, for example, when the brain detects that something is amiss, it seems to generate a mental hiccup of repeating thoughts (obsessions) or actions (compulsions) (Gehring et al., 2000). Brain scans of people

with OCD reveal elevated activity in specific brain areas during behaviors such as compulsive hand washing, checking, organizing, or hoarding (Insel, 2010; Mataix-Cols et al., 2004, 2005). The *anterior cingulate cortex,* a brain region that monitors our actions and checks for errors, is often especially hyperactive (Chavanne & Robinson, 2021) (**FIGURE 49.3**).

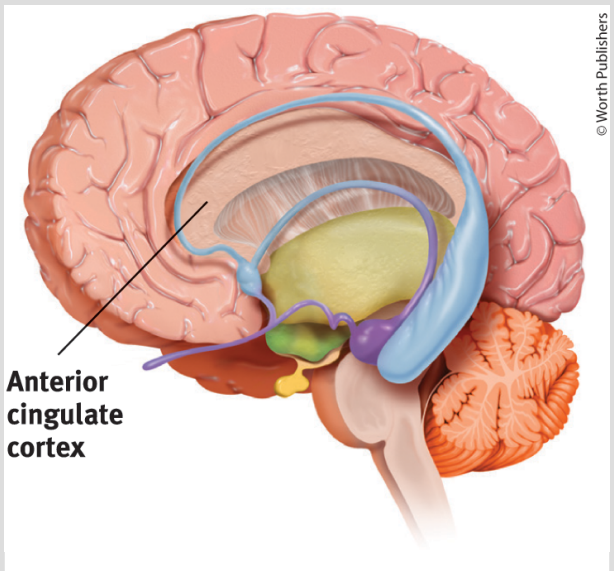

FIGURE 49.3 An obsessive-compulsive brain
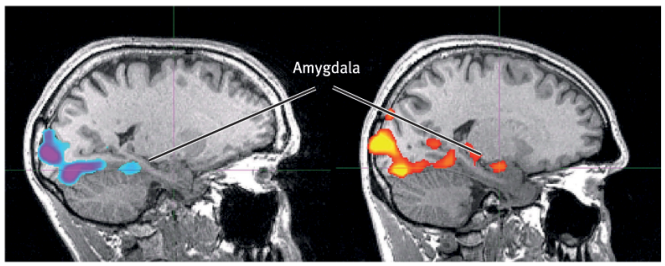
When people engaged in a challenging cognitive task, those with OCD showed the most activity in the anterior cingulate cortex in the brain's frontal lobe (Maltby et al., 2005).

Some antidepressant drugs dampen this fear circuit activity and its associated obsessive-compulsive behavior. Fears can also be blunted by giving people drugs as they recall and then rerecord ("reconsolidate") a traumatic experience (Kindt et al., 2009; Norberg et



al., 2008). Although they don't forget the experience, the associated emotion is largely erased.

Natural Selection

We seem biologically prepared to fear threats faced by our ancestors. Our specific phobias focus on particular fears such as spiders, snakes, and other animals; enclosed spaces and heights; storms and darkness. Those fearless about these occasional threats were less likely to survive and leave descendants. Nine-month-old infants attend more to sounds signaling ancient threats (hisses, thunder) than they do to sounds representing modern threats (a bomb exploding, breaking glass) (Erlich et al., 2013). It is easy to condition and hard to extinguish fears of such "evolutionarily relevant" stimuli (Coelho & Purkis, 2009; Davey, 1995; Öhman, 2009). Some of our modern fears (such as of flying) can also have an evolutionary explanation (a biological predisposition to fear confinement and heights).

Just as our specific phobias sometimes focus on dangers faced by our ancestors, so our compulsive acts typically exaggerate behaviors that contributed to our species' survival. Grooming had survival value. Gone wild, it becomes compulsive hair pulling. Washing up becomes relentless hand washing. And securing territorial boundaries becomes checking and rechecking already locked doors (Rapoport, 1989).

Alex Honnold Control subject

Left: Peter Bohler/Redux Pictures; right: Jane E. Joseph

Fearless The biological perspective helps us understand why most people fear heights more than Alex Honnold does. In 2017, he became the first person to free solo (climb without safety ropes) Yosemite National Park's massive El Capitan granite wall. (*Free Solo,* a documentary about this feat, won a 2019 Oscar.) When psychologist Jane Joseph showed Honnold fear-inducing images in the lab, an fMRI scan found his fear-processing amygdala minimally responsive (Donovan, 2019). (The red and yellow indicate increased amygdala activation in the control subject—also a rock climber—while Honnold's brain shows less activation in that region.)

and Somatic Symptom and Related Disorders

Learning Objectives

Test Yourself Answer these repeated Learning Objective Questions on your own (before "showing" the answers here, or checking the answers in Appendix D) to improve your retention of the concepts (McDaniel et al., 2009, 2015).

LOQ 49-1: How do generalized anxiety disorder, panic disorder, and specific phobias differ?

LOQ 49-2: What is *OCD?*

LOQ 49-3: What is *PTSD?*

LOQ 49-4: What is a *somatic symptom disorder?*

LOQ 49-5: How do learning, cognition, and biology contribute to the feelings and thoughts that mark anxiety disorders, OCD, PTSD, and somatic symptom disorders?

Terms and Concepts to Remember

Test Yourself Write down the definition in your own words, then check your answer.

anxiety disorders
social anxiety disorder
generalized anxiety disorder
panic disorder
specific phobia
obsessive-compulsive disorder (OCD)
posttraumatic stress disorder (PTSD)
trauma- and stressor-related disorders
somatic symptom disorder
illness anxiety disorder

Module Test

Test Yourself Answer the following questions on your own first, then "show" the answers here, or check your answers in Appendix E.

1. An episode of intense dread that can be accompanied by chest pains, choking, or other frightening sensations is called
   a. an obsession.
   b. a compulsion.
   c. a panic attack.
   d. a specific phobia.

2. Anxiety that takes the form of an irrational and maladaptive fear of a specific object, activity, or situation is called a _____ _____.

3. Marino became consumed with the need to clean the entire house and refused to participate in any other activities. His family consulted a therapist, who diagnosed him as having _____ - _____ disorder.

4. When a person with an anxiety disorder eases anxiety by avoiding or escaping a situation that inspires fear, this is called
   a. free-floating anxiety.
   b. reinforcement.
   c. an epigenetic mark.
   d. hypervigilance.

5. The learning perspective proposes that specific phobias are
   a. the result of individual genetic makeup.
   b. a way of repressing unacceptable impulses.
   c. conditioned fears.
   d. a symptom of having been abused as a child.

MODULE 50: Depressive Disorders and Bipolar Disorders

LOQ 50-1

How do depressive disorders and bipolar disorders differ?

What separates depression from sadness? We feel sad when bad things happen—a poor exam grade, a breakup, a job loss. But when feelings of despair or emptiness last for weeks (or even months), psychologists consider this more than just ordinary sadness—it may be depression.

> **"The first thing that goes is happiness. You cannot gain pleasure from anything."**
> — Andrew Solomon, *The Noonday Demon: An Atlas of Depression,* 2001

Have you ever been diagnosed with depression? If so, you are not alone. In one national survey, 27 percent of U.S. college students answered *Yes* (ACHA, 2022). If depressed, you might feel deeply discouraged about the future, dissatisfied with your life, or socially isolated. You may lack the energy to get things done, to see people, or even to force yourself out of bed. You may be unable to concentrate or eat. You may struggle to fall or stay asleep (Pan et al., 2022).

Occasionally, you may think about death and even wonder if you would be better off gone (Li et al., 2022). Perhaps academic success came easily to you before, but now you find that disappointing grades jeopardize your perfectionist goals (Levine et al., 2020). Maybe loneliness or a romantic breakup has plunged you into despair. And perhaps low self-esteem increases your brooding, worsening your self-torment (Orth et al., 2016). Comparing yourself to seemingly happy, successful others on social media, you may think it's just you feeling this way (Jordan et al., 2011). Most of us will have some direct or indirect experience with depression: Misery has more company than we think.

As anxiety can be a response to the threat of future loss, depression is often a response to past and current stress, such as family traumas or repeatedly experienced racism (Chen et al., 2022; Hankerson et al., 2022; Macjejewski et al., 2021). To feel bad in reaction to profoundly sad events, such as the loss of a friend or family member, is to be in touch with reality. In such times, depression is like a car's low-fuel light—a signal to stop and take appropriate measures. As one book title reminds us, there are "good reasons for bad feelings."

People with *major depressive disorder,* however, experience hopelessness and lethargy that doesn't always match the situation, and that lasts several weeks or months (Rottenberg & Hindash, 2015). *Persistent depressive disorder* (also called *dysthymia*) is similar, but with milder depressive symptoms that last 2 years or more. Those with

bipolar disorders (formerly called *manic-depressive disorder*) alternate between depression and overexcited hyperactivity.

> **"My life had come to a sudden stop. I was able to breathe, to eat, to drink, to sleep. I could not, indeed, help doing so; but there was no real life in me."** — Leo Tolstoy, *My Confession,* 1887

Biologically speaking, life's purpose is not constant happiness but survival and reproduction. Coughing, vomiting, and pain protect the body from dangerous toxins and stimuli. Similarly, depression compels us to slow us down and conserve energy (Beck & Bredemeier, 2016; Gershon et al., 2016). When we grind temporarily to a halt and reassess our life, as depressed people do, we can consider how to redirect our energy in ways that may reduce our depression (Watkins, 2008). There can be sense to some suffering.

> **"If someone offers you a pill that would make you happy 100 percent of the time, you should run fast in the other direction.... What good is a compass if it's always stuck on north?"** — Daniel Gilbert (Lambert, 2007)

Even temporary sadness helps people process and recall faces more accurately (Hills et al., 2017). Sadness can also help us be more cooperative, compassionate, and attuned to others (Gruber et al., 2011; Ong et al., 2017). It can enhance our critical thinking (and lessen our chances of being fooled) by increasing our attention to details

(Forgas, 2009, 2013, 2017). Bad moods sometimes serve good purposes. But sometimes depression becomes seriously maladaptive. How do we recognize the fine line between a blue mood and a depressive disorder?

Ask Yourself

Has student life ever made you feel down or depressed? What advice would you have for new students (perhaps advice you wish someone had given to you)?

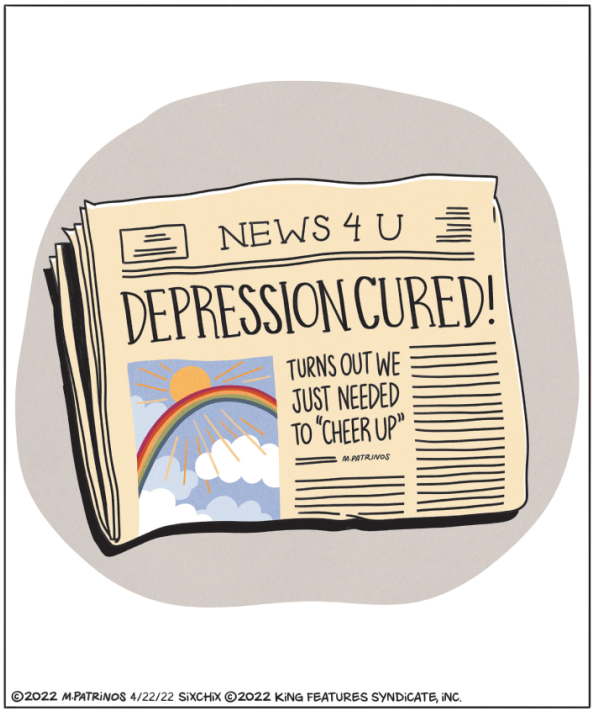
Depressive Disorders

Joy, contentment, sadness, and despair are different points on a continuum—points at which any of us may be found at any given moment. The difference between a blue mood after bad news and **major depressive disorder**—the most common of the **depressive disorders**—is like the difference between breathlessness after climbing a few flights of stairs and chronic breathing problems (**TABLE 50.1**).

TABLE 50.1 Diagnosing Major Depressive Disorder

The DSM-5-TR classifies major depressive disorder as the presence of at least five of the following symptoms over 2 weeks (must include depressed mood or reduced interest) (American Psychiatric Association, 2022).
• Depressed mood most of the time
• Dramatically reduced interest or enjoyment in most activities most of the time

- Significant challenges regulating appetite and weight
- Significant challenges regulating sleep
- Physical agitation or lethargy
- Feeling listless or with much less energy
- Feeling worthless, or feeling unwarranted guilt
- Problems in thinking, concentrating, or making decisions
- Thinking repetitively of death and suicide



Depression involves multiple symptoms.

Depression varies. You can be depressed in different ways and for different amounts of time. You can be depressed for 2 weeks or more, in the case of major depressive disorder, or for a much longer time

(but with milder symptoms) in the case of persistent depressive disorder. You might feel unusually depressed a week before your menses *(premenstrual dysphoric disorder),* experience parts of depression and anxiety at the same time *(mixed anxiety-depressive disorder),* or feel depressed alongside severe irritability that starts at a young age *(disruptive mood dysregulation disorder)* (American Psychiatric Association, 2022).

> **"Depression is a silent, slow motion tsunami of dark breaking over me."** — Effy Redman, "Waiting for Depression to Lift," 2017

Depression—the number-one reason people seek mental health services—is "a global health crisis," according to a World Psychiatric Association commission (Herrman et al., 2022). In surveys conducted in 15 countries, 5 percent of people reported experiencing a major depressive episode during the prior year (Vigo et al., 2022). U.S. rates were even higher, with 17 percent of adolescents and 8 percent of adults experiencing such an episode (SAMHSA, 2021). Worldwide, depression levels rose dramatically during the Covid-19 pandemic (Zhang & Chen, 2021). Younger adults, women, medical workers, people of color, and those who were unemployed were hardest hit (Fitzpatrick et al., 2020; Gruber et al., 2021; Rossi et al., 2020; Twenge & Joiner, 2020). Michelle Obama (2020) spoke for many: "There have been periods throughout this quarantine where I just have felt too low.... I am dealing with some form of low-grade depression."

©2022 M. Patrinos 4/22/22 SIXCHIX, King Features Syndicate, Inc.

If only it were so easy.

Bipolar Disorders

People with **bipolar disorders** have periods of extremely excited mood and increased energy that can last several days or more. Like depressive disorders, bipolar disorders take different forms depending on how severe the symptoms are and how long they last (see **FIGURE 50.1**). People with *bipolar I disorder,* the most severe form, experience a euphoric, talkative, highly energetic and overly ambitious state called **mania** that lasts a week or longer. Psychiatrist Kay Redfield Jamison described her mania: "When you're high it's tremendous. The ideas and feelings are fast and frequent like shooting stars, and you follow them until you find better and brighter ones" (Jamison, 1996).

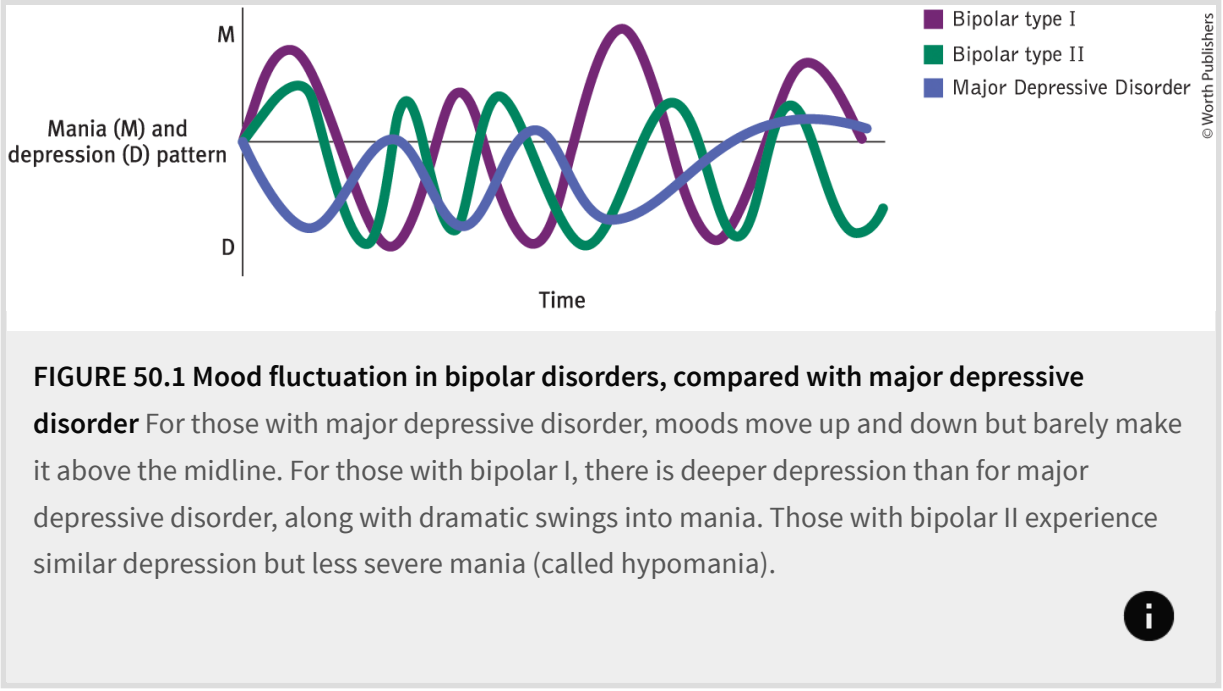


FIGURE 50.1 Mood fluctuation in bipolar disorders, compared with major depressive disorder For those with major depressive disorder, moods move up and down but barely make it above the midline. For those with bipolar I, there is deeper depression than for major depressive disorder, along with dramatic swings into mania. Those with bipolar II experience similar depression but less severe mania (called hypomania).

But before long, many people with bipolar I disorder can plunge into depression. Sometimes they go back and forth, experiencing *rapid cycling* between the highs and lows. Those with *bipolar II disorder* move between depression and a milder *hypomania*.

Life as a Two-Headed Beast: Bipolar, Abigail Southworth

Bipolar disorders Artist Abigail Southworth illustrated her experience of a bipolar disorder.

If depression is living in slow motion, mania is fast forward. Thinking fast feels good, but it also increases risk-taking (Chandler & Pronin, 2012; Pronin, 2013). During the manic phase, people with a bipolar disorder typically have less need for sleep. They show fewer sexual inhibitions. They set overly ambitious goals—like becoming famous or winning the Nobel Prize—and rarely follow through with them (Johnson, 2005). They may be excited and highly positive, no matter what the circumstances (Gruber, 2011). They have trouble regulating their emotions, which can lead to inappropriately persistent positive emotions (Gruber et al., 2019; Miola et al., 2022). Their speech is rapid, flighty, and hard to interrupt. They may ignore advice. Yet they might need assistance to prevent them from engaging in harmful behaviors, such as out-of-control spending, too-fast driving, or unsafe sex.

Mania's energy and flood of ideas can fuel creativity. Genes associated with high creativity increase the likelihood of a bipolar disorder, and risk factors for developing a bipolar disorder predict greater creativity (Taylor, 2017). George Frideric Handel (1685–1759), who may have experienced a bipolar disorder, composed his nearly 3-hour-long *Messiah* (1742) during 3 weeks of intense, creative energy (Keynes, 1980). Robert Schumann composed 51 musical works during 2 years of mania (1840 and 1849) but none during 1844, when he experienced severe depression (Slater & Meyer, 1959). Composers, artists, poets,

novelists, and entertainers seem especially prone to bipolar disorders (Jamison, 1993, 1996; Kaufman & Baer, 2002; Ludwig, 1995). Indeed, one analysis of over a million people showed that the only psychiatric condition linked to working in a creative profession was a bipolar disorder (Kyaga et al., 2013).

Axelle/Bauer-Griffin/Getty Images

Creativity and bipolar disorders There have been many creative artists, composers, writers, and musical performers with a bipolar disorder. Some struggle secretly, as did Mariah Carey for 17 years.

People in the United States are more likely than people in other countries to have been diagnosed with a bipolar disorder, especially among adolescents (GBD, 2022; Merikangas et al., 2011). From 2000 to

2010, U.S. children and adolescents were an astonishing 72 times more likely than English adolescents to receive a bipolar disorder diagnosis (James et al., 2014). The DSM-5-TR (2022) classifications became stricter, resulting in a reduced number of child and adolescent bipolar diagnoses.

Understanding Depressive Disorders and Bipolar Disorders

LOQ 50-2

How can the biological and social-cognitive perspectives help us understand depressive disorders and bipolar disorders?

Today's psychologists continue to investigate why people have depressive disorders and bipolar disorders, and to design more effective treatments and prevention strategies. Here, we focus on major depressive disorder. One research group summarized the facts that any theory of depression must explain (Lewinsohn et al., 1985, 1998, 2003):

- ***Behaviors and thoughts change with depression.*** People in a depressed mood become inactive and feel alone, empty, and without a meaningful future. They have more negative thoughts about themselves *(I am a failure),* the world *(everything is worthless),* and the future *(the future is hopeless).* Depression may be triggered by a sad or stressful event (LeMoult, 2020). Yet even

when nothing bad happens, people with major depressive disorder often feel a heavy sadness. They also recall and expect negative happenings (my team will lose, my grades will fall, my love will fail) (Zetsche et al., 2019).

- ***Depression is widespread, with women everywhere at greater risk.*** Worldwide, 280 million people have depressive disorders and 40 million people have a bipolar disorder (WHO, 2022). There is, however, a considerable depression *gender gap*. Globally, women's risk for major depressive disorder is roughly double men's (GBD, 2022). The gap is especially pronounced among adolescent girls (Kuehner, 2017; see also **FIGURE 50.2**). In general, women are more vulnerable to disorders involving internal states, such as depression, anxiety, and inhibited sexual desire. Women also experience more situations that increase their risk for depression, such as receiving less pay for equal work, experiencing sexual harassment and assault, juggling multiple roles, and more often caring for children and older family members (Freeman & Freeman, 2013). Men's disorders tend to be more external—alcohol use disorder, and disorders related to antisocial conduct and lack of impulse control. Women often get sadder than men do; men often get madder than women do.
- ***Depression sometimes returns.*** For many people, depression comes and, after sustained struggle, it often goes. But for about half of these people, the depression returns (Curry et al., 2011; Klein & Kotov, 2016). For about 20 percent, the condition will be chronic (Klein, 2010).

- ***Stress and negative events often precede depression.*** About 1 person in 4 diagnosed with depression has experienced significant loss or trauma, such as a loved one's death, a ruptured marriage, a physical assault, or a lost job (LeMoult, 2020). Moving to a new culture also increases risk for depression, especially among younger people who have not yet formed their identities (Zhang et al., 2013). And childhood maltreatment and emotional abuse doubles a person's risk of later adult depression (Nelson et al., 2017).
- ***Compared with generations past, depression strikes earlier and more often, with the highest rates among older teens and young adults*** (Cross-National Collaborative Group, 1992; Kessler et al., 2010; Olfson et al., 2015). From 2010 to 2020, depression rates doubled among U.S. 12- to 17-year-olds (SAMHSA, 2021).
- ***Most people with depression can recover on their own and thrive.*** Therapy often speeds recovery. But even without professional help, many people recover amazingly well, do not experience future depression, and achieve "optimal well-being" (Rottenberg & Kashdan, 2022). An enduring recovery is more likely if: The first episode strikes later in life, there were no previous episodes, the person experiences minimal physical or psychological stress, and there is ample social support (Fuller-Thomson et al., 2016).

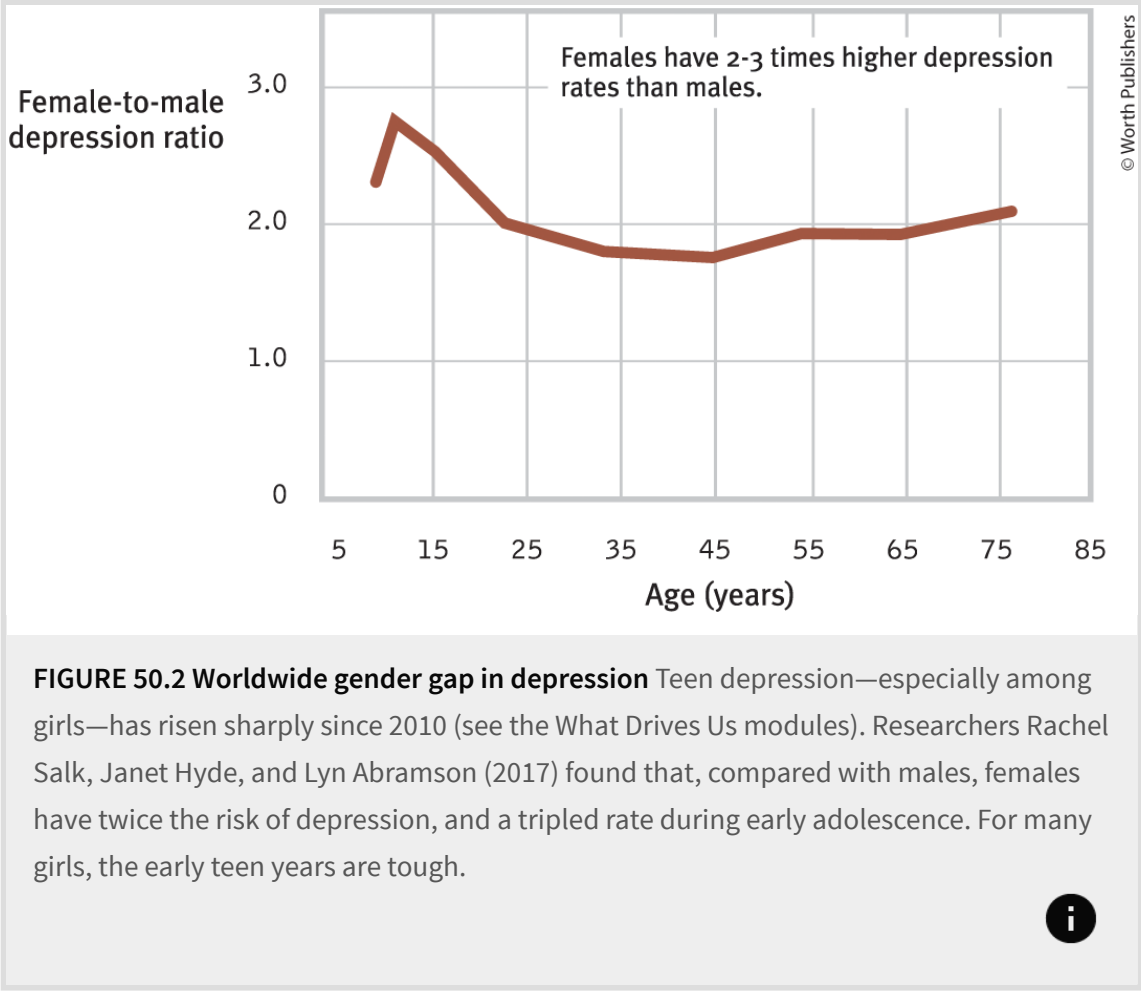

FIGURE 50.2 Worldwide gender gap in depression Teen depression—especially among girls—has risen sharply since 2010 (see the What Drives Us modules). Researchers Rachel Salk, Janet Hyde, and Lyn Abramson (2017) found that, compared with males, females have twice the risk of depression, and a tripled rate during early adolescence. For many girls, the early teen years are tough.

The Biological Perspective

Depression is a whole-body disorder. It involves genetic predispositions and biochemical imbalances, as well as negative thoughts and a gloomy mood.

Genetic Influences

Major depressive disorder and bipolar disorders run in families. As one researcher noted, emotions are "postcards from our genes" (Plotkin, 1994). The risk of being diagnosed with one of these

disorders increases if your parent or sibling has the disorder (Sullivan et al., 2000; Weissman et al., 2016). If one identical twin is diagnosed with major depressive disorder, the chances are about 1 in 2 that at some time the other twin will be, too. If one identical twin has a bipolar disorder, the chances of a similar diagnosis for the co-twin are even higher—7 in 10—even for twins raised apart (DiLalla et al., 1996).

Summarizing the major twin studies, two research teams independently estimated the *heritability*—the extent to which individual differences are attributable to genes—of major depressive disorder at nearly 40 percent (Kendler et al., 2018; Polderman et al., 2015; see also **FIGURE 50.3**). But nurture matters, too. A Swedish national study examined children who had a biological parent with depression. In families where at least one child was raised by the parent with depression and another child was adopted into a different family, those raised in the adoptive homes "had a significantly reduced risk for major depression" (Kendler et al., 2020).

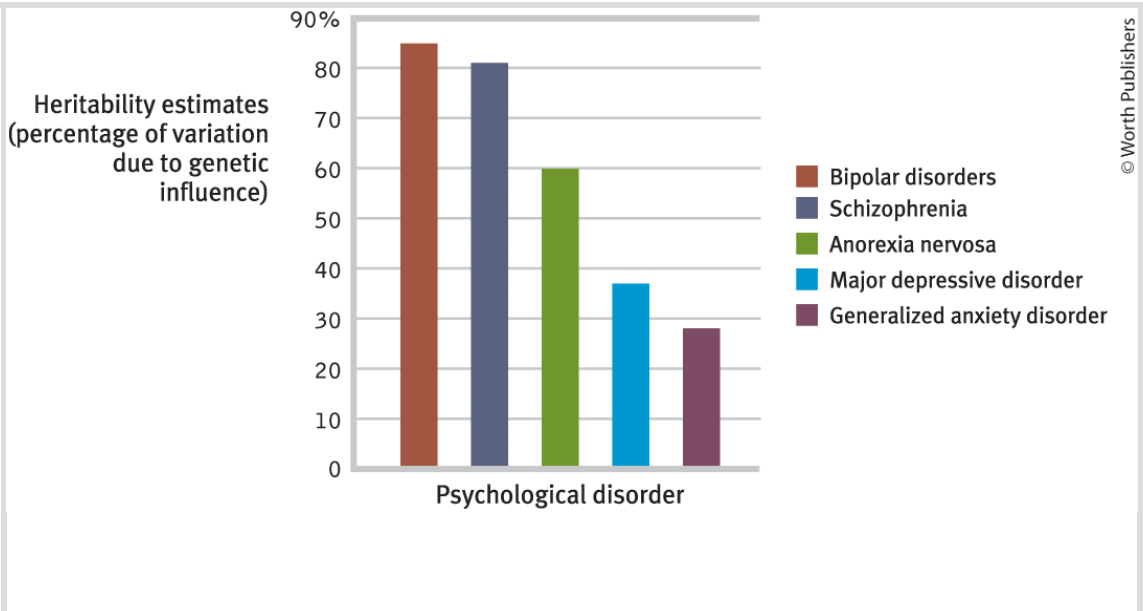

FIGURE 50.3 The heritability of various psychological disorders Using aggregated data from studies of identical and fraternal twins, researchers estimated the heritability of bipolar disorders, schizophrenia, anorexia nervosa, major depressive disorder, and generalized anxiety disorder (Bienvenu et al., 2011). (Heritability was calculated by a formula that compares the extent of similarity among identical versus fraternal twins.)

To tease out the genes that put people at risk for depression, researchers may use *linkage analysis.* First, geneticists find families in which the disorder appears across several generations. Next, the researchers look for differences in DNA from affected and unaffected family members. Linkage analysis points them to a chromosome neighborhood; "A house-to-house search is then needed to find the culprit gene" (Plomin & McGuffin, 2003). But depression is a complex condition. *Many genes* work together, each producing small effects that interact with other factors to increase depression risk. Today's researchers are analyzing the entire human genome to identify genetic variations in depressive and bipolar disorders that may open the door to more personalized and effective drug therapy (Howard et al., 2019; Palmer et al., 2022; Peterson, 2021).

Brain Structure and Activity

Nearly 150 studies have identified unique brain circuitry linked with depression (Zhukovsky et al., 2021). Neuroscientists have also discovered altered brain structures in people with a bipolar disorder, including thin frontal lobes and enlarged fluid-filled ventricles (Angelescu et al., 2021; Zhu et al., 2022).

Scanning devices offer a window into the brain's activity during depressed and manic states. One study gave 13 elite Canadian swimmers the wrenching experience of watching a video of the swim in which they failed to make the Olympic team or failed at the Olympic games (Davis et al., 2008). Functional MRI scans showed the disappointed swimmers experiencing brain activity patterns similar to those of people with depressed moods.

Many studies have found diminished brain activity during slowed-down depressive states, and more activity during periods of mania (**FIGURE 50.4**). Depression can cause the brain's reward centers to become less active, whereas bipolar mania can increase activity in these centers (Dutra et al., 2015; Nusslock et al., 2012).

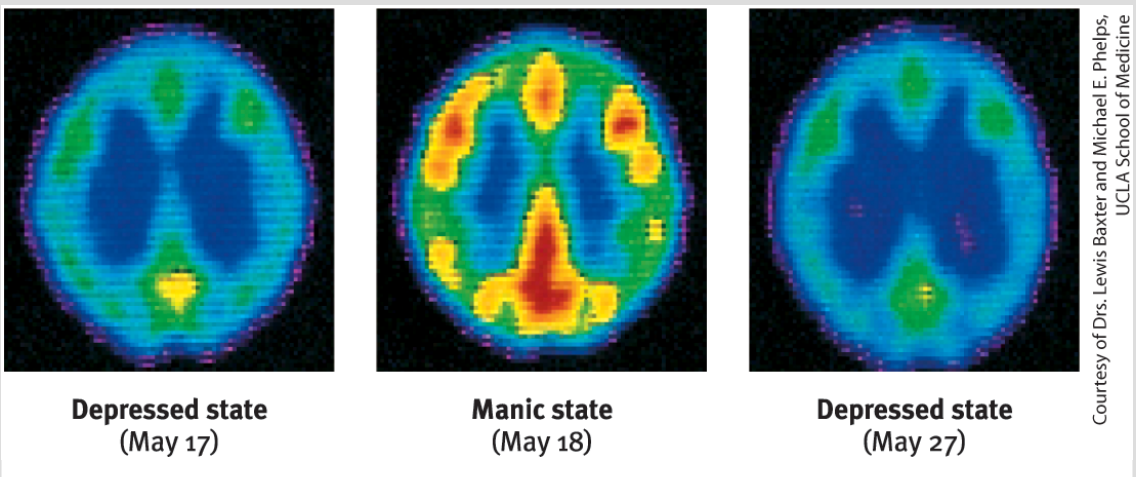

FIGURE 50.4 The ups and downs of a bipolar disorder These top-facing PET scans show that brain energy consumption rises and falls with the patient's emotional changes. Red areas are where the brain rapidly consumes *glucose,* an important energy source.

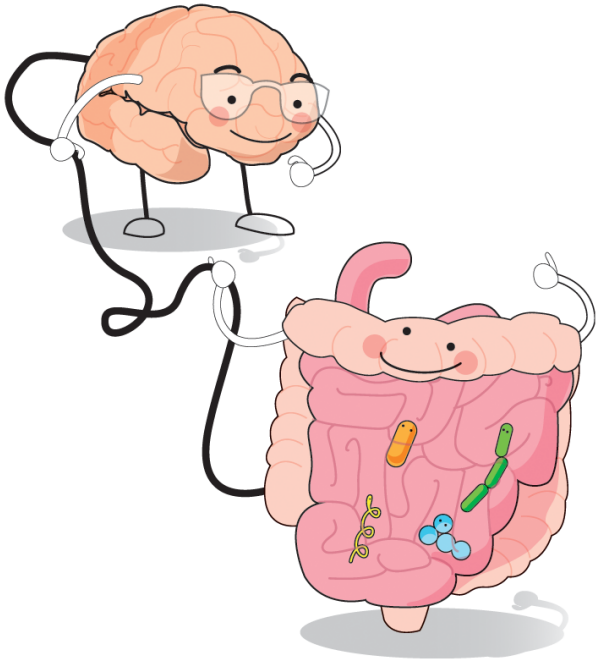

At least two neurotransmitter systems are at work during the periods of altered brain activity that accompany major depressive disorder and bipolar disorders. *Norepinephrine,* which increases arousal and boosts mood, is scarce during depression and overabundant during mania. Drugs that decrease mania reduce norepinephrine. *Serotonin* is also often scarce or inactive during depression, increasing when depression fades (Carver et al., 2008; Svensson et al., 2021). The story of neurotransmitters is still being written, as other researchers have begun to question the reliability of associations between neurotransmitter levels and depression (Moncrieff et al., 2022).

Drugs that relieve depression tend to increase norepinephrine or serotonin supplies by blocking either their reuptake (as Prozac, Zoloft, and Paxil do with serotonin) or their chemical breakdown. Repetitive physical exercise, such as jogging, reduces depression in part because it increases serotonin, which affects mood and arousal (Morres et al., 2019; Wipfli et al., 2011). To run away from a bad mood, some people use their own two feet.

Nutritional Effects

Certain foods, such as refined sugar and red meat, have been linked to *inflammation* (a persistent immune response that can affect many body systems). Inflammation and depression often go hand in hand (Mousten et al., 2022; Osimo et al., 2019). Conversely, what's good for the body is also good for the brain and mind. People who eat a healthy "Mediterranean diet" (heavy on vegetables, fish, whole grains, and

olive oil) reduce inflammation levels, thereby diminishing their risk of depression (Kaplan et al., 2015; Psaltopoulou et al., 2013; Rechenberg, 2016). Excessive alcohol use also correlates with depression, partly because depression can increase alcohol use but mostly because alcohol misuse *leads* to depression (Fergusson et al., 2009).

© Worth Publishers

Minding the gut Does food modify mood? Digestive system bacteria produce serotonin and other neurotransmitters that influence emotions. Although some researchers think the happy gut/happy brain relationship is overhyped, healthy, diverse gut microbes predict less risk of anxiety, depression, and bipolar disorders (Nikolova et al., 2021). There is, it seems, a biochemistry behind "gut feelings."

The Social-Cognitive Perspective

Biological influences contribute to depression, but in the nature–nurture dance, our life experiences also play a part. Diet, drugs, stress, and other environmental influences lay down epigenetic marks, those molecular genetic tags that can turn certain genes on or off. Animal studies suggest long-lasting epigenetic influences on depression (Nestler, 2011).

Thinking matters, too. The *social-cognitive perspective* explores how people's assumptions and expectations influence what they perceive. Many depressed people have intensely negative views of themselves, their situation, and their future (Nieto et al., 2020). Norman, a Canadian university professor, recalled his depression this way:

> I [despaired] of ever being human again. I honestly felt subhuman, lower than the lowest vermin. Furthermore, I was self-deprecatory and could not understand why anyone would want to associate with me, let alone love me.... I was positive that I was a fraud and a phony and that I didn't deserve my Ph.D.... I didn't deserve the research grants I had been awarded; I couldn't understand how I had written books and journal articles.... I must have conned a lot of people. (Endler, 1982, pp. 45–49)

Expecting the worst, depressed people magnify bad experiences and minimize good ones (Wenze et al., 2012). Their *self-defeating beliefs* and their *negative explanatory style* feed their depression.

Negative Thoughts and Negative Moods

Do you agree or disagree with this statement: "I feel frequently overwhelmed by all I have to do"? In a national survey, 55 percent of women and 28 percent of men entering U.S. colleges and universities agreed (Stolzenberg et al., 2020). Relationship stresses also affect teen girls more than boys (Hamilton et al., 2015). Why are women nearly twice as vulnerable as men to depression, and twice as likely to take antidepressant drugs (Pratt et al., 2017)?

This higher risk may relate to women's tendency to *ruminate*—to overthink, fret, or brood (Nolen-Hoeksema, 2003; Spinoven et al., 2018). Staying focused on a problem—thanks to the continuous activation of an attention-sustaining frontal lobe area—can be adaptive (Altamirano et al., 2010; Andrews & Thomson, 2009a,b). But relentless, self-focused **rumination** can distract us, intensify negative emotion, and increase depression symptoms (Johnson et al., 2016; Stefanovic et al., 2022; Yang et al., 2017). We can even ruminate about our excessive rumination—by thinking too much about how we're thinking about something too much.

Comparisons can also feed rumination. Lonely Lori scrolls through her social media feed and sees Maria having a blast at a party, Angelique enjoying a family vacation, and Amira looking super in a swimsuit. In response, Lori broods: "My life is terrible" and "Why can't I look like her?" (See the What Drives Us modules for the debate over whether social media-enabled comparisons have fueled the rise in teen girls' depression.)

Rumination runs wild We all think about our flaws. But dwelling constantly on negative thoughts—particularly negative thoughts about ourselves—makes it difficult to feel confident and self-assured. People sometimes seek therapy to reduce their rumination.

But why do life's unavoidable failures lead only some people to become depressed? The answer lies partly in their *explanatory style*—who or what they blame for their failures. Think of how you might feel if you failed a test. If you externalize the blame ("What an unfair test!"), you are more likely to feel angry. If you blame yourself, you probably will feel stupid and depressed ("I can't do anything right!").

Depression-prone people respond to bad events in an especially self-focused, self-blaming way (LeMoult & Gotlib, 2019). As **FIGURE 50.5**

illustrates, they explain bad events in terms that are *stable, global,* and *internal.*

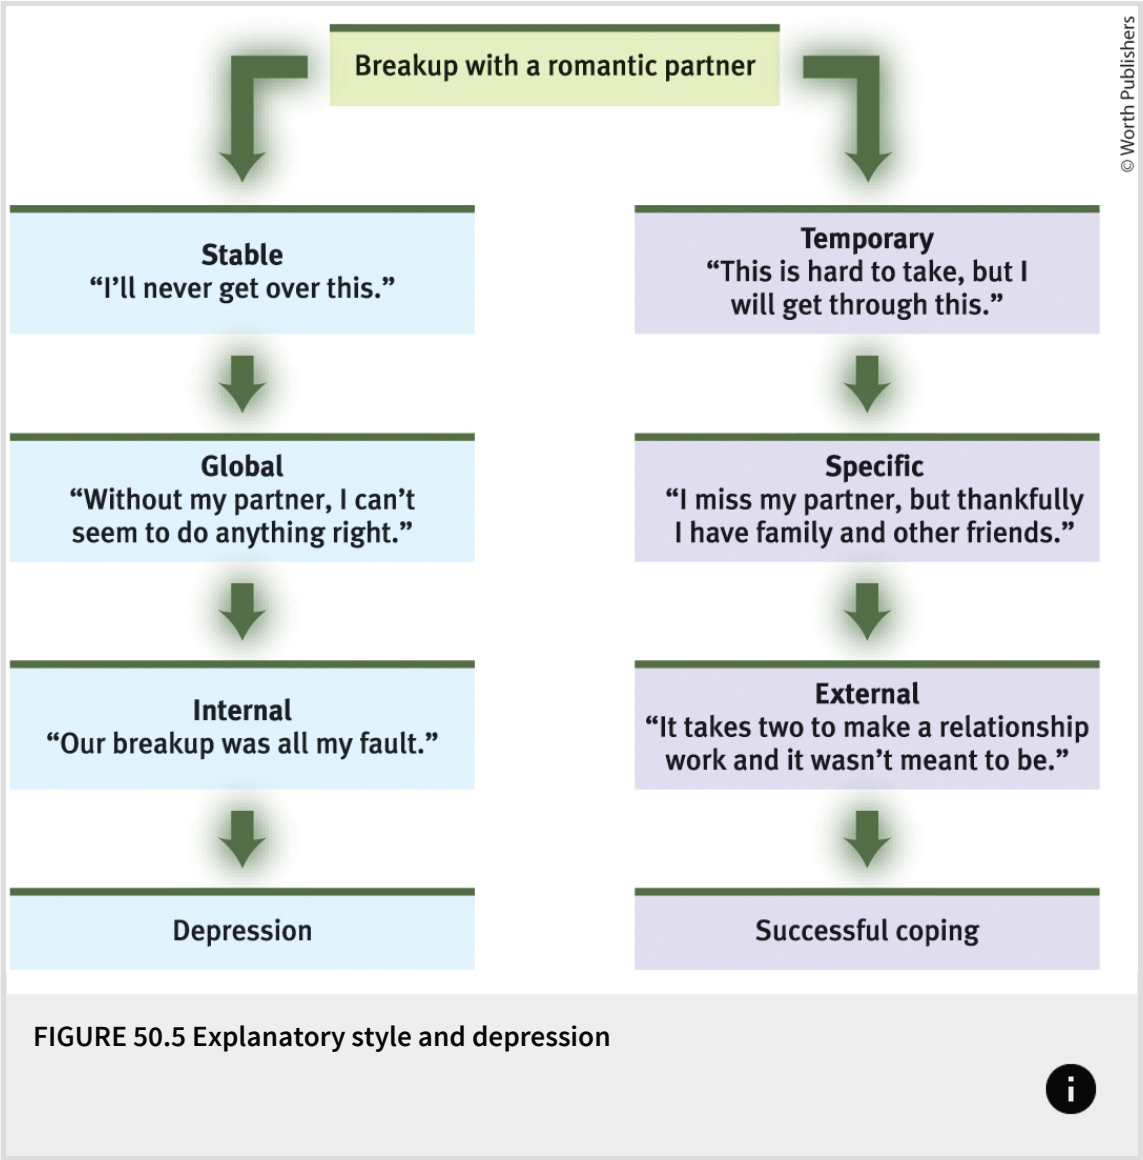

FIGURE 50.5 Explanatory style and depression

Self-defeating beliefs may arise from *learned helplessness,* the hopelessness and passive resignation that humans and other animals learn when they experience uncontrollable painful events (Maier & Seligman, 2016). Pessimistic, overgeneralized, self-blaming attributions may create a depressing sense of hopelessness

(Abramson et al., 1989; Groß et al., 2017). As researcher Martin Seligman has noted, “A recipe for severe depression is preexisting pessimism encountering failure” (1991, p. 78).

What, then, might we expect of new college students who exhibit a pessimistic explanatory style? Lauren Alloy and her colleagues (1999) monitored several hundred students every 6 weeks for 2.5 years. Among those identified as having a pessimistic thinking style, 17 percent had a first episode of major depression, as did only 1 percent of those who began college with an optimistic thinking style. This massive difference was no fluke: A large follow-up study showed that extreme feelings of hopelessness increased the odds of major depression tenfold (Liu et al., 2021).

Why is depression so common among young Westerners? Seligman (1991, 1995) has pointed to the rise of individualism and the decline of commitment to religion and family. In non-Western cultures, where close-knit relationships and cooperation are the norm, major depressive disorder is less common and less tied to self-blame for failure (De Vaus et al., 2018; Ferrari et al., 2013). In Japan, for example, depressed people instead tend to report feeling shame over letting others down (Draguns, 1990).

Critics note a chicken-and-egg problem nesting in the social-cognitive explanation of depression. Which comes first? The pessimistic explanatory style, or the depressed mood? The negative explanations *coincide* with a depressed mood, and they are *indicators* of depression.

But do they *cause* depression? Experiments reveal that a depressed mood triggers pessimism. Temporarily putting people in a bad or sad mood makes their memories, judgments, and expectations more pessimistic. Memory researchers call this tendency to recall experiences that fit our current good or bad mood *state-dependent memory*.

Depression's Vicious Cycle

Depression is both a cause and an effect of stressful experiences that disrupt our sense of who we are and why we matter. Such disruptions can lead to brooding, which amplifies negative feelings. Being withdrawn, self-focused, and complaining can, in turn, elicit rejection (Furr & Funder, 1998; Gotlib & Hammen, 1992). Indeed, people in the throes of depression are at high risk for divorce, job loss, and other stressful life events. Weary of the person's fatigue, hopeless attitude, and negativity, a spouse may threaten to leave, or a boss may begin to question the person's competence. (This provides another example of gene–environment interaction: People genetically predisposed to depression more often experience depressing events.) Rejection and depression feed each other. Misery may love another's company, but company does not love another's misery.

We can now assemble the pieces of the depression puzzle (**FIGURE 50.6**): (1) Stressful experiences interpreted through (2) a ruminating, pessimistic explanatory style create (3) a hopeless, depressed state that (4) hampers the way the person thinks and acts. This, in turn,

fuels (1) further stressful experiences such as rejection. Depressed people “are prone to behaviors that reinforce their depressive symptoms” (Hart et al., 2021). Depression is a snake that bites its own tail.

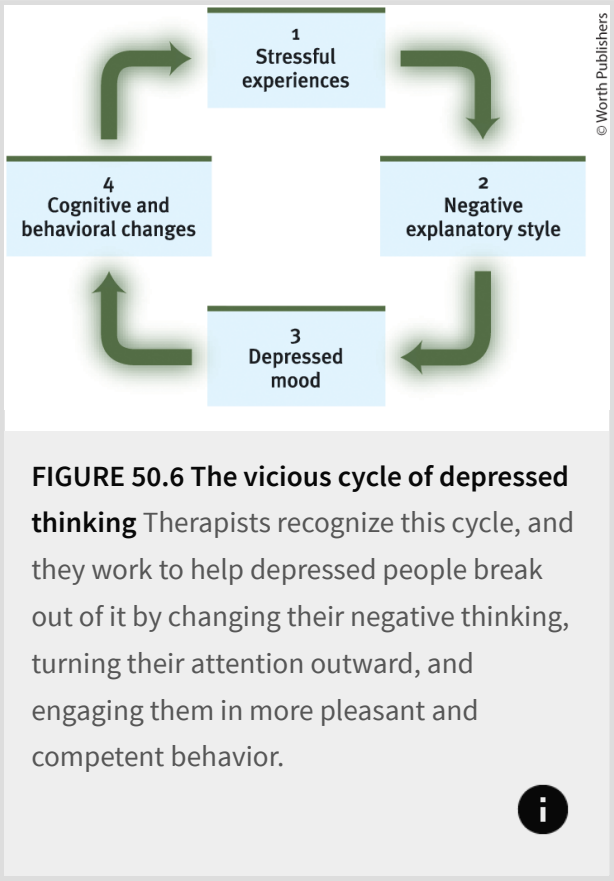

FIGURE 50.6 The vicious cycle of depressed thinking Therapists recognize this cycle, and they work to help depressed people break out of it by changing their negative thinking, turning their attention outward, and engaging them in more pleasant and competent behavior.

It is a cycle we can all recognize. Bad moods feed on themselves: When we feel down, we think negatively and remember bad experiences. Britain’s Prime Minister Winston Churchill called depression a “black dog” that periodically hounded him. U.S. President Abraham Lincoln was so withdrawn and brooding as a young man that his friends feared he might take his own life (Kline, 1974). Poet Emily Dickinson was so afraid of bursting into tears in

public that she spent much of her adult life in seclusion (Patterson, 1951). As their lives remind us, "depression" can be an anagram for "I pressed on." Many people struggle through depression and regain their capacity to love, to work, and to succeed.

Module 50: Depressive Disorders and Bipolar Disorders

Learning Objectives

Test Yourself Answer these repeated Learning Objective Questions on your own (before "showing" the answers here, or checking the answers in Appendix D) to improve your retention of the concepts (McDaniel et al., 2009, 2015).

LOQ 50-1: How do depressive disorders and bipolar disorders differ?

LOQ 50-2: How can the biological and social-cognitive perspectives help us understand depressive disorders and bipolar disorders?

Terms and Concepts to Remember

Test Yourself Write down the definition in your own words, then check your answer.

major depressive disorder
depressive disorders
bipolar disorders
mania
rumination

Module Test

Test Yourself Answer the following questions on your own first, then "show" the answers here, or check your answers in Appendix E.

1. The gender gap in depression refers to the finding that _____ (men's/women's) risk of depression is roughly double that of _____ (men's/women's).

2. U.S. rates of bipolar disorders _____ between 1990 and 2019.
   a. increased.
   b. decreased.
   c. were consistent.

3. Treatment for depression often includes drugs that increase supplies of the neurotransmitters _____ and _____.

4. Psychologists who emphasize how negative perceptions, beliefs, and thoughts enable depression are working within the _____-_____ perspective.

MODULE 51: Schizophrenia

During their most severe periods, people with **schizophrenia** live in a private inner world, preoccupied with the strange ideas and images that haunt them. The word itself means "split" *(schizo)* "mind" *(phrenia).* It refers *not* to a multiple identity split but rather to the mind's split from reality. People with schizophrenia have disturbed perceptions and beliefs, disorganized speech, and diminished, inappropriate emotions and actions. Schizophrenia is the chief example of a **psychotic disorder**.

Symptoms of Schizophrenia

LOQ 51-1

What patterns of perceiving, thinking, and feeling characterize schizophrenia?

Schizophrenia comes in varied forms. People with schizophrenia display symptoms that are *positive* (*inappropriate* behaviors are *present*) or *negative* (*appropriate* behaviors are *absent*). Those with positive symptoms may experience disturbed perceptions, talk in disorganized and deluded ways, or exhibit inappropriate laughter, tears, or rage. Those with negative symptoms may exhibit an absence of emotion in their voices, expressionless faces, or mute and rigid bodies.

Disturbed Perceptions and Beliefs

People with schizophrenia sometimes *hallucinate*—they see, hear, feel, taste, or smell things that exist only in their minds. Most often, the hallucinations are voices, which sometimes make insulting remarks or give orders. The voices may tell the person that they are bad or that they must hurt themselves. Imagine your own reaction if a dream broke into your waking consciousness, making it hard to separate your experience from your imagination. When the unreal seems real, the resulting perceptions are at best bizarre, at worst terrifying.

Art by someone with schizophrenia After his schizophrenia diagnosis, Michigan artist Craig Geiser said he "started drawing as a way to relax and escape the real world" (Geiser, 2021). Medication and therapy have helped

quiet Geiser's hallucinations and delusions, enabling him to lead a meaningful life (Geiser, 2019).

Hallucinations are false *perceptions.* People with schizophrenia also have disorganized, fragmented thinking, often distorted by false *beliefs* called **delusions**. If they have *paranoid* delusions, they may interpret events in ways that make them feel threatened or pursued (Trotta et al., 2021).

One cause of disorganized thinking may be a breakdown in *selective attention.* Normally, we have a remarkable capacity to give our undivided attention to one set of sensory stimuli while filtering out others. People with schizophrenia are easily distracted by tiny unrelated stimuli, such as the grooves on a brick or tones in a voice. As Elyn Saks (2007) described it, "every sight, every sound, every smell coming at you carries equal weight; every thought, feeling, memory, and idea presents itself to you with an equally strong and demanding intensity." This selective-attention difficulty is but one of dozens of cognitive differences associated with schizophrenia (Reichenberg & Harvey, 2007).

Disorganized Speech

Maxine, a young woman with schizophrenia, believed she was Mary Poppins. Communicating with Maxine was difficult because her thoughts spilled out in no logical order. Her biographer, Susan

Sheehan (1982, p. 25), observed her saying aloud to no one in particular, “This morning, when I was at Hillside [Hospital], I was making a movie. I was surrounded by movie stars.... Is this room painted blue to get me upset? My grandmother died four weeks after my eighteenth birthday.”

Jumbled ideas may make no sense even within sentences, forming what is known as *word salad.* One young man begged for “a little more allegro in the treatment,” and suggested that “liberationary movement with a view to the widening of the horizon” will “ergo extort some wit in lectures.”

Diminished or Inappropriate Emotions

The expressed emotions of schizophrenia are often utterly inappropriate, split off from reality (Kring & Caponigro, 2010). Maxine laughed after recalling her grandmother’s death. On other occasions, she cried when others laughed, or became angry for no apparent reason. Others with schizophrenia lapse into an emotionless *flat affect* state of no apparent feeling.

Most also have an *impaired theory of mind*—they have difficulty reading other peoples’ facial expressions and states of mind (Bora & Pantelis, 2016). Unable to understand others’ mental states, those with schizophrenia struggle to feel sympathy and compassion (Bonfils et al., 2016). These emotional deficiencies occur early in the illness and have a genetic basis (Bora & Pantelis, 2013). *Motor behavior* may also

be inappropriate and disruptive. Those with schizophrenia may experience *catatonia,* characterized by motor behaviors ranging from a physical stupor (remaining motionless for hours), to senseless, compulsive actions (such as continually rocking or rubbing an arm), to severe and dangerous agitation.

As you can imagine, such disturbed perceptions and beliefs, disorganized speech, and out of place emotions profoundly disrupt social and work relationships. During their most severe periods, people with schizophrenia live in a private inner world, preoccupied with illogical ideas and unreal images. As with other disorders, many have sleep problems, which can increase night eating and obesity (Baglioni et al., 2016; Palmese et al., 2011). Given a supportive environment and medication, over 40 percent of people with schizophrenia will have periods of a year or more of normal life experience (Jobe & Harrow, 2010). But only 1 in 7 will have a full and enduring recovery (Jääskeläinen et al., 2013).

Onset and Development of Schizophrenia

LOQ 51-2

How do *chronic schizophrenia* and *acute schizophrenia* differ?

An estimated 20 million people worldwide—about 1 in 270—have schizophrenia (WHO, 2019). This disorder knows no national boundaries and it typically strikes as young people are maturing into adulthood (TABLE 51.1). Men tend to be diagnosed more often than women, and to be struck earlier and with more severity (Aleman et al., 2003; Eranti et al., 2013; Picchioni & Murray, 2007).

TABLE 51.1 Onset of Psychological Disorders

A digest of nearly 200 studies of more than 700,000 people reveals the *median* age (midpoint of the recorded ages) at which various disorders are first diagnosed (Solmi et al., 2022). In each case the most frequent *(modal)* age of onset is somewhat younger than the median age shown below.

Disorder	Median Age of Onset
Neurodevelopmental disorders	12
Anxiety disorders	17
Eating disorders	18
Obsessive-compulsive disorder	19
Substance use disorders	25
Schizophrenia	25
Personality disorders	25
Depressive disorders	30

When schizophrenia is a slow-developing process, called **chronic schizophrenia**, recovery is doubtful (Harrison et al., 2001; Jääskeläinen et al., 2013). This was the case with Maxine, whose schizophrenia took a slow course, emerging after a long history of social difficulties and poor school performance (MacCabe et al., 2008). Although people with both chronic and *acute schizophrenia* can exhibit positive or negative symptoms, social withdrawal—a negative symptom—is often found among those with chronic schizophrenia (Kirkpatrick et al., 2006). Men more often exhibit negative symptoms and chronic schizophrenia (Räsänen et al., 2000).

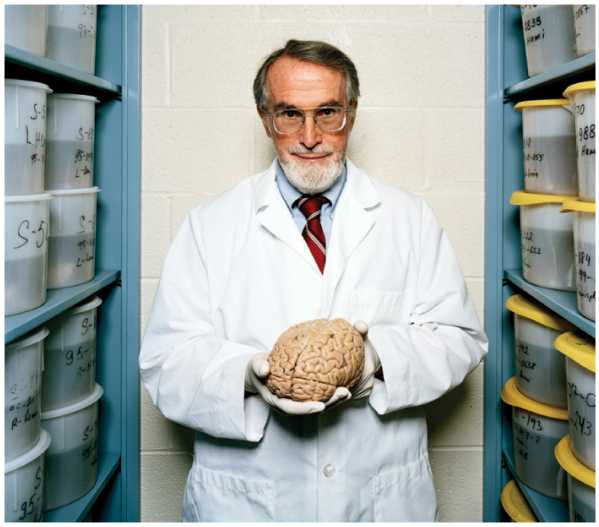
When previously well-adjusted people develop schizophrenia rapidly following particular life stresses, this is called **acute schizophrenia**, and recovery is much more likely. They more often have positive symptoms that respond to drug therapy (Fenton & McGlashan, 1991, 1994; Fowles, 1992).

Understanding Schizophrenia

Schizophrenia is one of the most heavily researched psychological disorders. Studies now link it with abnormal brain tissue and genetic predispositions. Schizophrenia is a disease of the brain manifested in symptoms of the mind.

Brain Abnormalities

LOQ 51-3



What brain abnormalities are associated with schizophrenia?

Might chemical imbalances in the brain underlie schizophrenia? Scientists have long known that strange behavior can have strange chemical causes. The saying "as mad as a hatter" is often thought to refer to the psychological deterioration of British hatmakers whose brains, it was later discovered, were slowly poisoned by the mercury-laden felt material (Smith, 1983). Could schizophrenia symptoms have a similar biochemical key? Scientists are searching for blood proteins that might predict schizophrenia onset (Chan et al., 2015). And they are tracking the mechanisms by which chemicals produce hallucinations and other symptoms.

Dopamine Overactivity

One possible answer emerged when researchers examined schizophrenia patients' brains after death. They found an excess number of *dopamine* receptors, including a sixfold excess for the dopamine receptor D4 (Seeman et al., 1993; Wong et al., 1986). Such a hyper-responsive dopamine system may intensify brain signals in schizophrenia, creating positive symptoms such as hallucinations and paranoia (Maia & Frank, 2017). Drugs that block dopamine receptors often lessen these symptoms. Drugs that increase dopamine levels,

such as nicotine, amphetamines, and cocaine, sometimes intensify them (Basu & Basu, 2015; Farnia et al., 2014).

© Chris Mueller/Redux Pictures

Storing and studying brains Psychiatrist E. Fuller Torrey has collected the brains of hundreds of people with disorders such as schizophrenia and bipolar disorders who died as young adults.

Abnormal Brain Activity and Anatomy

Abnormal brain activity and brain structures accompany schizophrenia. Some people diagnosed with schizophrenia have abnormally low brain activity in the frontal lobes, areas that help us reason, plan, and solve problems (Morey et al., 2005; Pettegrew et al., 1993; Resnick, 1992). Brain scans also show a noticeable decline in the brain waves that reflect synchronized neural firing in the frontal lobes (Spencer et al., 2004; Symond et al., 2005).

One study took PET scans of brain activity while people with schizophrenia were hallucinating (Silbersweig et al., 1995). When participants heard a voice or saw something, their brain became vigorously active in several core regions. One was the thalamus, the structure that filters incoming sensory signals and transmits them to the brain's cortex. Another PET scan study of people with paranoia found increased activity in the amygdala, a fear-processing center (Epstein et al., 1998).

In schizophrenia, fluid-filled brain cavities called *ventricles* become enlarged; cerebral tissue also shrinks (Goldman et al., 2009; van Haren et al., 2016). People often inherit these brain differences. If one affected identical twin shows brain abnormalities, the odds are at least 1 in 2 that the other twin's brain will have them (van Haren et al., 2012). Some studies have even found these abnormalities in people who *later* developed the disorder (Karlsgodt et al., 2010). The greater the brain shrinkage, the more severe the thought disorder (Collinson et al., 2003; Nelson et al., 1998; Shenton, 1992).

Smaller-than-normal areas may include the cortex, the hippocampus, and the corpus callosum connecting the brain's two hemispheres (Arnone et al., 2008; Bois et al., 2016). Often, the thalamus is also smaller than normal, which may explain why people with schizophrenia have difficulty filtering sensory input and focusing attention (Andreasen et al., 1994; Ellison-Wright et al., 2008). Schizophrenia also tends to involve a loss of neural connections across the brain network (Bohlken et al., 2016; Kambeitz et al., 2016).

The bottom line: Schizophrenia involves not one isolated brain abnormality but problems with several brain regions and their interconnections (Andreasen, 1997, 2001; Arnedo et al., 2015).

Prenatal Environment and Risk

LOQ 51-4

What prenatal events are associated with increased risk of developing schizophrenia?

What causes these brain abnormalities in people with schizophrenia? Some scientists point to prenatal development or delivery (Fatemi & Folsom, 2009; Walker et al., 2010). Risk factors include low birth weight, maternal diabetes, older paternal age, and oxygen deprivation during delivery (King et al., 2010). Famine may also increase risks. People conceived during the peak of World War II's Dutch famine and during the famine of 1959 to 1961 in eastern China later developed schizophrenia at twice the normal rate (St. Clair et al., 2005; Susser et al., 1996). And extreme maternal stress may be a culprit: A large Israeli study showed that maternal exposure to terror attacks during pregnancy doubled children's risk of schizophrenia (Weinstein et al., 2018).

Let's consider another possible culprit. Might a midpregnancy viral infection impair fetal brain development (Brown & Patterson, 2011)? Can you imagine some ways to test this fetal-virus idea? Scientists have asked the following:

- ***Are people at increased risk of schizophrenia if their country experienced a flu epidemic during the middle of their fetal development?*** The repeated answer has been *Yes* (Mednick et al., 1994; Murray et al., 1992; Wright et al., 1995).
- ***Are people born in densely populated areas, where viral diseases spread more readily, at greater risk for schizophrenia?*** The answer, confirmed in a study of 1.75 million Danes, has again been *Yes* (Jablensky, 1999; Mortensen, 1999).
- ***Are those born during the winter and spring months—those who were in utero during the fall-winter flu season—also at increased risk?*** The answer is again *Yes* (Fox, 2010; Schwartz, 2011; Torrey & Miller, 2002; Torrey et al., 1997).
- ***In the Southern Hemisphere, where the seasons are the reverse of the Northern Hemisphere, are the months of above-average pre-schizophrenia births similarly reversed?*** Again, the answer has been *Yes*. In Australia, people born between August and October are at greater risk. But people born in the Northern Hemisphere who later moved to Australia still have a greater risk if they were born between January and March (McGrath et al., 1995; McGrath & Welham, 1999).
- ***Are those who report being sick with influenza during pregnancy more likely to bear children who develop schizophrenia?*** In one study of nearly 8000 women, the answer was *Yes.* The schizophrenia risk increased from the customary 1 percent to about 2 percent—but only when infections occurred during the second trimester (Brown et al., 2000). Maternal influenza

infection during pregnancy affects brain development in monkeys as well (Short et al., 2010).

- ***Do blood samples collected from pregnant participants whose offspring develop schizophrenia show higher-than-normal levels of antibodies that suggest a viral infection?*** In several studies—including one that collected blood samples from some 20,000 pregnant participants—the answer has again been *Yes* (Brown et al., 2004; Buka et al., 2001; Canetta et al., 2014).

These converging lines of evidence suggest that fetal-virus infections contribute to the development of schizophrenia. They also strengthen the World Health Organization's (2017) recommendation that those who are pregnant be given high priority for the seasonal flu vaccine.

Genetic Factors

LOQ 51-5

How do genes influence schizophrenia? What factors may be early warning signs of schizophrenia in children?

Fetal-virus infections may increase the odds that a child will develop schizophrenia. But many women get the flu during their second trimester of pregnancy, and only 2 percent of them bear children who develop schizophrenia. Why are only some children at risk? Might some people be more genetically vulnerable to schizophrenia? *Yes.* The roughly 1-in-270 lifetime odds of any person being diagnosed with

schizophrenia become about 1 in 10 among those who have a sibling or parent with the disorder. If the affected sibling is an identical twin, the odds increase to nearly 1 in 2 (FIGURE 51.1). Those odds remain the same even when the twins are raised apart (Plomin et al., 1997). (Only about a dozen such cases are on record.)

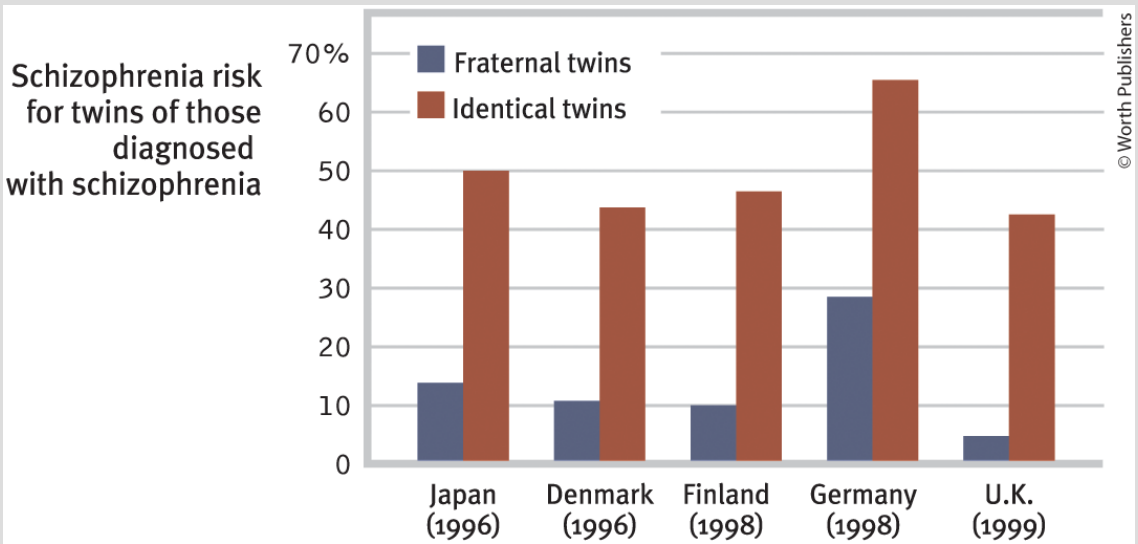


FIGURE 51.1 Risk of developing schizophrenia The lifetime risk of developing schizophrenia varies with a person's genetic relatedness to someone who has this disorder. Worldwide, barely more than 1 in 10 fraternal twins, but some 5 in 10 identical twins, share a schizophrenia diagnosis. (Data from Gottesman, 2001; Hilker et al., 2018.)

Remember, though, that identical twins share more than their genes. They also share a prenatal environment. About two-thirds share a placenta and the blood it supplies; the other third have separate placentas. Shared placentas matter. If the co-twin of an identical twin with schizophrenia shared the placenta, the chances of developing the disorder are 6 in 10. If the identical twins had separate placentas, the

co-twin's chances of developing schizophrenia drop to 1 in 10 (Davis et al., 1995; Davis & Phelps, 1995; Phelps et al., 1997). Twins who share a placenta are more likely to share the same prenatal viruses. So perhaps shared germs as well as shared genes produce identical twin schizophrenia similarities (FIGURE 51.2).

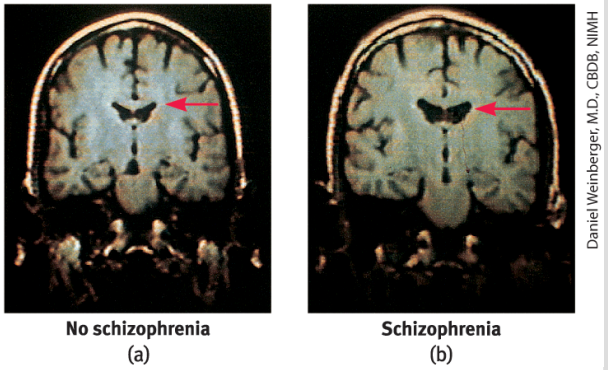

FIGURE 51.2 Schizophrenia in only one identical twin When identical twins differ, only the brain of the twin with schizophrenia typically has enlarged, fluid-filled cranial cavities (b) (Suddath et al., 1990). The difference between the twins implies some nongenetic factor, such as a virus, is also at work.

Adoption studies help untangle genetic and environmental influences. Children adopted by someone who develops schizophrenia do not "catch" the disorder. Rather, adopted children have an elevated risk if a *biological* parent has schizophrenia (Gottesman, 1991). Genes indeed matter.

Although genes matter, the genetic formula is not straightforward as with inheritance of eye color. Schizophrenia is influenced by (no surprise by now) many genes, each with small effects (Binder, 2019; Weinberger, 2019). The search is on for specific genes that, in some combination, predispose schizophrenia-inducing brain abnormalities. In the largest genetic studies of schizophrenia, scientists analyze worldwide data from the genomes of tens of thousands of people with and without schizophrenia (Lam et al., 2019; Pardiñas et al., 2018). One analysis found 176 genome locations linked with this disorder, some affecting dopamine and other neurotransmitters. Another study of more than 100,000 people—nearly half with schizophrenia and the rest without—identified 413 schizophrenia-associated genes (Huckins et al., 2019).

Moreover, as we see in so many different contexts, nature and nurture interact. *Epigenetic* factors influence whether genes will be expressed. Like hot water activating a tea bag, environmental factors such as viral infections, nutritional deprivation, and maternal or severe life stress can "turn on" the genes that put some of us at higher risk for schizophrenia. Identical twins' differing histories in the womb and beyond explain why they may show differing gene expressions (Dempster et al., 2013; Walker et al., 2010). Our heredity and our life experiences work together. Neither hand claps alone.

Thanks to our expanding understanding of genetic and brain influences on disorders such as schizophrenia, the general public increasingly recognizes the potency of biological factors in psychiatric

disorders (Pescosolido et al., 2010). So, will future scientists develop genetic tests that reveal who is at risk—for schizophrenia, or for other psychological disorders? If so, will people undergo testing for themselves, their embryos, or their children to determine risk? And how will they use that information? In this twenty-first-century world, such questions await answers.

Environmental Triggers for Schizophrenia

If prenatal viruses and genetic predispositions do not, by themselves, cause schizophrenia, neither do family or social factors alone. It remains true, as Susan Nicol and Irving Gottesman (1983) noted over three decades ago, that "no environmental causes have been discovered that will invariably, or even with moderate probability, produce schizophrenia in persons who are not related to" a person with schizophrenia.

Hoping to identify environmental triggers of schizophrenia, researchers have compared the experiences of high-risk children (for example, those with relatives with schizophrenia) and low-risk children. In one 2.5-year study that followed 163 teens and early-twenties adults who had two relatives with schizophrenia, the 20 percent of participants who developed schizophrenia showed social withdrawal or other abnormal behavior before the onset of the disorder (Johnstone et al., 2005). Researchers identified other possible early warning signs, including a mother whose schizophrenia was severe and long-lasting; birth complications (often involving oxygen

deprivation and low birth weight); frequent childhood hospitalizations for viral and other infections; separation from parents; short attention span and poor muscle coordination; disruptive or withdrawn behavior; emotional unpredictability; poor peer relations and solo play; and childhood physical, sexual, or emotional abuse (Abel et al., 2010; Debost et al., 2019; Freedman et al., 1998; Schiffman et al., 2001; Susser, 1999; Welham et al., 2009).

***

Few of us can relate to the strange thoughts, perceptions, and behaviors of schizophrenia. Sometimes our thoughts jump around, but we rarely talk nonsensically. Occasionally we feel unjustly suspicious of someone, but we do not fear that the world is plotting against us. Often our perceptions err, but rarely do we see or hear things that are not there. We feel regret after laughing at someone's misfortune, but we rarely giggle in response to our own bad news. At times we just want to be alone, but we do not retreat into fantasy worlds. However, millions of people worldwide do talk strangely, experience delusions, hear nonexistent voices, see things that are not there, laugh or cry at inappropriate times, or withdraw into private imaginary worlds. The quest to solve the cruel puzzle of schizophrenia therefore continues, more vigorously than ever.

Ask Yourself

Can you recall a time when you heard something or someone casually (and inaccurately) described as "schizophrenic"? Now that you know more about this disorder, how might you correct such descriptions?

Retrieval Practice

RP-1 A person with schizophrenia who has _____ (positive/negative) symptoms may have an expressionless face and toneless voice. Those with _____ (positive/negative) symptoms are likely to experience delusions.

RP-2 What factors contribute to the onset and development of schizophrenia?

schizophrenia
psychotic disorders
delusion
chronic schizophrenia
acute schizophrenia

Module Test

Test Yourself Answer the following questions on your own first, then "show" the answers here, or check your answers in Appendix E.

1. Valencia exclaims, "The weather has been so schizophrenic lately; it's hot one day and freezing the next!" In addition to being insensitive, this comparison is inaccurate. Why?

2. A person with positive symptoms of schizophrenia is most likely to experience
   a. catatonia.
   b. delusions.
   c. withdrawal.
   d. flat emotion.

3. People with schizophrenia may hear voices urging self-destruction, an example of a(n) _____.

4. Chances for recovery from schizophrenia are best when
   a. onset is sudden, in response to stress.
   b. deterioration occurs gradually, during childhood.
   c. no environmental causes can be identified.
   d. there is a detectable brain abnormality.

MODULE 52: Dissociative, Personality, and Eating Disorders

Next we will consider the dissociative, personality, and eating disorders.

Dissociative Disorders

LOQ 52-1

What are *dissociative disorders,* and why are they controversial?

Among the most bewildering disorders are the rare **dissociative disorders**, in which a person's conscious awareness *dissociates* (separates) from painful memories, thoughts, and feelings. The result may be a *dissociative fugue state,* a sudden loss of memory or change in identity, often in response to an overwhelmingly stressful situation (Harrison et al., 2017). Such was the case for one Vietnam War veteran who was haunted by his comrades' deaths, and who had left his World Trade Center office shortly before the 9/11 terrorist attack. Later, he disappeared. Six months later, when he was discovered in a Chicago homeless shelter, he reported no memory of his identity or family (Stone, 2006).

Dissociative Identity Disorder

Dissociation itself is not so rare. Any one of us may have a fleeting sense of being unreal, of being separated from our body, of watching ourselves as if in a movie. A massive dissociation of self from ordinary consciousness occurs in **dissociative identity disorder (DID)**, in which two or more distinct identities—each with its own voice and mannerisms—seem to control a person's behavior. Thus, the person may be prim and proper one moment, loud and flirtatious the next. Typically, the original identity denies any awareness of the other(s).

Collection Christophel/Alamy Stock Photo

Multiple identities in the movies Chris Sizemore's story, told in the 1957 book and movie *The Three Faces of Eve,* gave early visibility to what is now called dissociative identity disorder. This controversial disorder continues to influence modern media, as in the 2019 movie *Glass,* where James McAvoy's character (pictured here) displays 24 different identities.

Understanding Dissociative Identity Disorder

Skeptics question DID. Are clinicians who discover multiple identities merely triggering role-playing by fantasy-prone people in a particular social context (Giesbrecht et al., 2008, 2010; Lynn et al., 2014; Merskey, 1992)? After all, clients do not enter therapy saying "Allow me to introduce myselves." Instead, charge the critics, some therapists go fishing for multiple identities: "Have you ever felt like another part of you does things you can't control?" "Does this part of you have a name? Can I talk to the angry part of you?" Once clients permit a therapist to talk, by name, "to the part of you that says those angry things," they begin acting out the fantasy. Like actors who lose themselves in their roles, vulnerable patients may "become" the parts they are acting out. The result may be the experience of another self. Or perhaps dissociative identities are simply a more extreme version of the varied "selves" we sometimes present—a goofy self around our friends, a subdued self around our employer.

Skeptics also find it suspicious that the disorder has such a short and localized history. Between 1930 and 1960, the number of North American DID diagnoses averaged 2 per decade. By the 1980s, when the *Diagnostic and Statistical Manual of Mental Disorders* (DSM) contained the first formal code for this disorder, the number had exploded to more than 20,000 (McHugh, 1995). The average number of displayed identities also mushroomed—from 3 to 12 per patient (Goff & Simms, 1993). And although diagnoses have been increasing in countries where DID has been publicized, the disorder is much less

prevalent outside North America (Lilienfeld, 2017). As skeptics note, once a disorder is made "official," reported cases of it tend to soar.

MBR/KRT/Newscom

Widespread dissociation Shirley Mason was a psychiatric patient diagnosed with dissociative identity disorder. Her life formed the basis of the bestselling book, *Sybil* (Schreiber, 1973), and of two movies. The book and movies' popularity contributed to increased DID diagnoses. Audio recordings later revealed that Mason's psychiatrist manipulated her and that she did not actually have the disorder (Nathan, 2011).

Despite some hoaxes, other researchers and clinicians believe DID is a real disorder. They cite findings of distinct body and brain states associated with differing identities (Putnam, 1991). Abnormal brain anatomy and activity can also accompany DID. Brain scans show shrinkage in areas that aid memory and detection of threat (Vermetten et al., 2006). Heightened activity appears in brain areas associated with the control and inhibition of traumatic memories (Elzinga et al., 2007).

Both the psychodynamic and learning perspectives have interpreted DID symptoms as ways of coping with anxiety. Some psychodynamic theorists see them as defenses against the anxiety caused by the eruption of unacceptable impulses. In this view, a second identity enables the discharge of forbidden impulses. Learning theorists see dissociative disorders as behaviors reinforced by anxiety reduction.

Some clinicians include dissociative disorders under the umbrella of posttraumatic stress disorder as a natural, protective response to traumatic experiences during childhood (Brand et al., 2016; Spiegel, 2008). Many people being treated for DID recall being physically, sexually, or emotionally abused as children (Gleaves, 1996; Lilienfeld et al., 1999). Critics wonder, however, whether such recollections are false memories (Kihlstrom, 2005; McNally, 2007). So the scientific debate continues.

> **"Though this be madness, yet there is method in 't."** — William Shakespeare, *Hamlet,* 1600

Ask Yourself

Do you ever flip between displays of different aspects of your identity depending on the situation? How is your experience similar to and different from the described symptoms of dissociative identity disorder?

Retrieval Practice

RP-1 The psychodynamic and learning perspectives agree that dissociative identity disorder symptoms are ways of dealing with anxiety. How do their explanations differ?

ANSWERS IN APPENDIX E

Personality Disorders

LOQ 52-2

What are the three clusters of personality disorders? What behaviors and brain activity characterize antisocial personality disorder?

The inflexible and enduring behavior patterns of **personality disorders** interfere with social functioning. These 10 disorders in the DSM-5-TR tend to form three clusters (**TABLE 52.1**):

- In Cluster A, people appear ***eccentric or odd,*** as in the suspiciousness of *paranoid personality disorder*; the social detachment of *schizoid personality disorder*; or the magical thinking of *schizotypal personality disorder*.
- In Cluster B, people appear ***dramatic, emotional, or erratic,*** as in the unstable, attention-getting *borderline personality disorder;* the self-focused and self-inflating *narcissistic personality disorder;* the excessively emotional *histrionic personality disorder;* and—what we next discuss as an in-depth example—the callous, and often dangerous, *antisocial personality disorder.*
- In Cluster C, people appear ***anxious or fearful,*** as in the fearful sensitivity to rejection that predisposes the withdrawn *avoidant personality disorder;* the clinging behavior of *dependent personality disorder;* and the preoccupation with orderliness, perfectionism, and control that characterizes *obsessive-compulsive personality disorder.*

TABLE 52.1 Personality Disorders

The DSM-5-TR identifies 10 personality disorders (APA, 2022).
Cluster A • **Paranoid personality disorder:** suspiciousness; distrust of others • **Schizoid personality disorder:** social detachment; limited emotional expression • **Schizotypal personality disorder:** intense social discomfort; distorted cognitions or perceptions; behavioral eccentricity
Cluster B • **Borderline personality disorder:** impulsivity; unstable relationships and self-image

- **Narcissistic personality disorder:** grandiosity; admiration-seeking behavior; deficient empathy
- **Histrionic personality disorder:** extreme emotional expression; a need for attention
- **Antisocial personality disorder:** indifference to (and willingness to violate) others' rights; impulsiveness; criminal behavior

Cluster C

- **Avoidant personality disorder:** social inhibition; feeling inadequate; sensitivity to criticism
- **Dependent personality disorder:** submissive behavior; emotional neediness
- **Obsessive-compulsive personality disorder:** a fixation on orderliness; the need for perfection and control

Antisocial Personality Disorder

People with **antisocial personality disorder**, usually male, can display symptoms by age 8. Their lack of conscience becomes plain before age 15, as they begin to lie, steal, fight, or display unrestrained sexual behavior (Cale & Lilienfeld, 2002). Not all children with these traits become antisocial adults, and for many males, antisocial behavior often subsides after adolescence (Moffitt, 2018). (Note that *antisocial* means socially harmful and remorseless, not merely unsociable.) Those who do develop the disorder—about half—will generally act in violent or otherwise criminal ways, be unable to keep a job, and behave irresponsibly toward family members (Farrington, 1991).

But criminality is not an essential component of antisocial behavior (Skeem & Cooke, 2010). And many criminals do not exhibit antisocial personality disorder; rather, they show responsible concern for their friends and family members. In contrast with most criminals, people with antisocial personality disorder (sometimes called *sociopaths* or

psychopaths) are more socially deficient. They often exhibit less *emotional intelligence*—the ability to understand, manage, and perceive emotions (Ermer et al., 2012; Gillespie et al., 2019).

Leo Cullum/Cartoon Stock

"Thursday is out. I have jury duty."

Many criminals, like this one, display a sense of conscience and responsibility in other areas of their life, and thus do not exhibit antisocial personality disorder.

Antisocial personalities behave impulsively, and then feel and fear little (Fowles & Dindo, 2009). Their impulsivity can have horrific consequences, including homicide (Camp et al., 2013; Fox & DeLisi, 2019). Consider the case of Tommy Lynn Sells. He said he killed his first victim when he was 15. He felt little regret then or later. During his years of crime, he brutally murdered at least 17 adults and children. "I am hatred," Sells told one interviewer while on death row (ABC, 2014). "When you look at me, you look at hate."

John Mantha/Reuters/Newscom

No remorse Bruce McArthur, a 66-year-old landscaper shown here in a courtroom sketch, was convicted in 2019 of killing eight people over 8 years. He often targeted men who were gay, immigrants, or experiencing homelessness, storing their remains in boxes at his job sites. McArthur exhibited the extreme lack of remorse that marks antisocial personality disorder.

Understanding Antisocial Personality Disorder

Antisocial personality disorder is woven of both biological and psychological strands. Twin and adoption studies reveal that biological relatives of people with antisocial and unemotional tendencies are at increased risk for antisocial behavior (Frisell et al., 2012; Kendler et al., 2015). People with antisocial personalities sometimes spread their genes to future generations by marrying others who have antisocial personalities (B. Weiss et al., 2017). No single gene codes for a complex behavior such as crime. But genes that predispose lower mental ability and self-control predict a higher crime risk (Wertz et al., 2018). As with other disorders, geneticists have also identified specific genes that are more common in those

with antisocial personality disorder (Gunter et al., 2010; Tielbeek et al., 2017). The genes that put people at risk for antisocial behavior also put people at risk for substance use disorders (Dick, 2007).

The genetic vulnerability of people with antisocial tendencies appears as low arousal in response to threats. Awaiting aversive events, such as electric shocks or loud noises, they show little autonomic nervous system arousal (Hare, 1975; Ling et al., 2019). Long-term studies show that their stress hormone levels were lower than average as teenagers, before they had ever committed a crime (FIGURE 52.1). And those who were slow to develop conditioned fears at age 3 were also more likely to commit a crime later in life (Gao et al., 2010). Likewise, preschool boys who later become aggressive or antisocial adolescents tend to be impulsive, uninhibited, unconcerned with social rewards, and low in anxiety (Caspi et al., 1996; Tremblay et al., 1994).

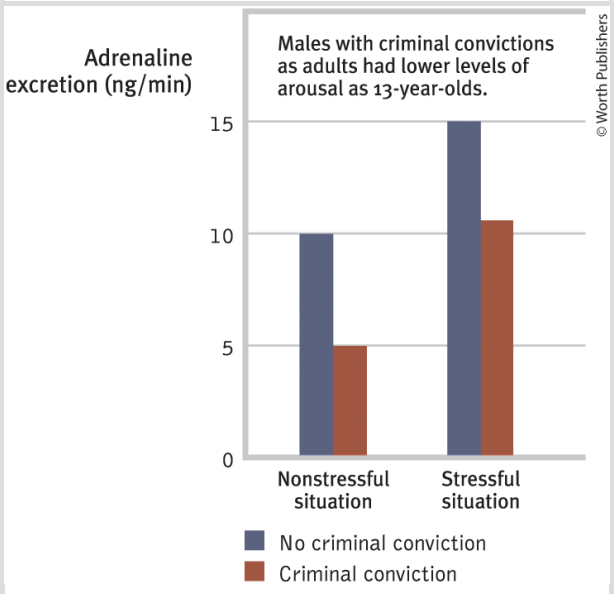

FIGURE 52.1 Cold-blooded arousability and risk of crime Researchers measured levels of

the stress hormone adrenaline in two groups of 13-year-old Swedish boys, and followed up on them as young adults. Those who would later be convicted of a crime as 18- to 26-year-olds showed relatively low arousal when they were younger, in both stressful and nonstressful situations. (Data from Magnusson, 1990.)

Traits such as fearlessness and dominance can be adaptive. If channeled in more productive directions, fearlessness may lead to athletic stardom, adventurism, or courageous heroism (Costello et al., 2018; Patton et al., 2018). Indeed, 42 U.S. presidents exhibited higher than usual fearlessness and dominance (Lilienfeld et al., 2012, 2016). Patient S. M., a 49-year-old woman with amygdala damage, showed fearlessness and impulsivity but also heroism: She gave a man in need her only coat and scarf, and donated her hair to the Locks of Love charity after befriending a child with cancer (Lilienfeld et al., 2017). Lacking a sense of social responsibility, however, the same disposition may produce a cool con artist or killer (Lykken, 1995).

Brain structure matters, too: People with antisocial criminal tendencies have a smaller-than-usual amygdala, which controls emotions, and a smaller and thinner brain cortex (Carlisi et al., 2020; Pardini et al., 2014). The frontal lobes are also less active, as shown by PET scans of 41 murderers' brains compared with those from people of similar age and sex (Raine, 1999, 2005; **FIGURE 52.2**). The frontal lobes help control impulses. The reduced activation was especially

apparent in those who murdered impulsively. In a follow-up study, Adrian Raine and his team (2000) found that violent repeat offenders had 11 percent less frontal lobe tissue than is typical. This helps explain why people with antisocial personality disorder exhibit marked deficits in frontal lobe cognitive functions, such as planning, organization, and inhibition (Morgan & Lilienfeld, 2000). Compared with people who feel and display empathy, their brains also respond less to facial displays of others' distress, which may contribute to their lower emotional intelligence (Deeley et al., 2006).

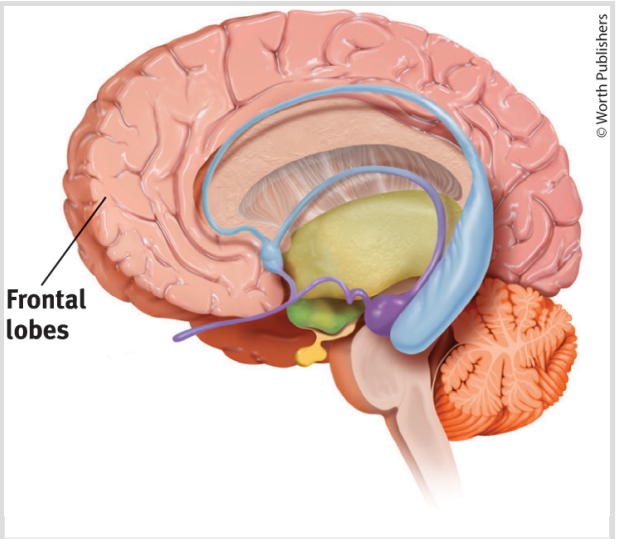

FIGURE 52.2 Murderous minds Researchers have found reduced activation in a murderer's frontal lobes. This brain area (shown in a left-facing brain) helps curb impulsive, aggressive behavior (Raine, 1999).

Genetic influences often combine with negative environmental factors —such as childhood abuse, family instability, or poverty—to wire the brain (Dodge, 2009). This gene–environment combination also occurs

in chimpanzees, which, like humans, vary in antisocial (mean/bold/disinhibited) tendencies (Latzman et al., 2017). In another Raine-led study (1996), researchers checked criminal records on nearly 400 Danish men at ages 20 to 22. All these men either had biological risk factors at birth (such as premature birth) or came from family backgrounds marked by poverty and family instability. The researchers then compared each of these two groups with a third *biosocial* group (people whose lives were marked by *both* those biological and social risk factors). The biosocial group had double the risk of committing a crime. Similar findings emerged from a famous study that followed 1037 children for a quarter-century: Two combined factors—childhood maltreatment and a gene that altered neurotransmitter balance—predicted antisocial problems (Caspi et al., 2002). Neither "bad" genes alone nor a "bad" environment alone predisposed later antisocial behavior. Rather, genes predisposed some children to be more sensitive to maltreatment. Within "genetically vulnerable segments of the population," environmental influences matter—for better or for worse (Belsky & Pluess, 2009; Moffitt, 2005).

With antisocial behavior—as with so much else—nature and nurture interact. Once again, the biopsychosocial perspective helps us understand the whole story. To further investigate the neural basis of antisocial personality disorder, neuroscientists are exploring the antisocial brain (Brazil & Buades-Rotger, 2020). Shown emotionally evocative photographs, such as a man holding a knife to a woman's throat, criminals with antisocial personality disorder display blunted heart rate and perspiration responses, and less activity in brain areas

that typically respond to emotional stimuli (Harenski et al., 2010; Kiehl & Buckholtz, 2010). They also have a larger and hyperreactive dopamine reward system, which predisposes their impulsive drive to do something rewarding despite the consequences (Buckholtz et al., 2010; Glenn et al., 2010). Such data provide another reminder: Everything psychological is also biological.

Retrieval Practice

RP-2 How do biological and psychological factors contribute to antisocial personality disorder?

ANSWERS IN APPENDIX E

Eating Disorders

LOQ 52-3

What are the three main eating disorders, and how do biological, psychological, and social-cultural influences make some people more vulnerable to them?

Our bodies are naturally disposed to maintain a steady weight, including storing energy for times when food becomes unavailable. But sometimes psychological influences overwhelm biological wisdom. This becomes painfully clear in three eating disorders.

- In **anorexia nervosa,** people—most often adolescent girls, but some women, men, and boys as well—starve themselves. Anorexia often begins as an attempt to lose weight, but the dieting becomes a habit (Steinglass et al., 2018). Regardless of their actual weight, a person with anorexia feels fat, fears being fat, and focuses obsessively on losing weight, sometimes exercising excessively.
- In **bulimia nervosa,** a cycle of repeated episodes of binge eating alternates with behaviors to compensate, such as vomiting, laxative use, fasting, or excessive exercise (Wonderlich et al., 2007). Unlike anorexia, bulimia is marked by weight fluctuations within or above typical ranges, making the disorder easier to hide.
- Those with **binge-eating disorder**—the world's most common eating disorder—are preoccupied with food and engage in significant bouts of bingeing, followed by remorse. But they do not purge, fast, or exercise excessively (Santomauro et al., 2021).

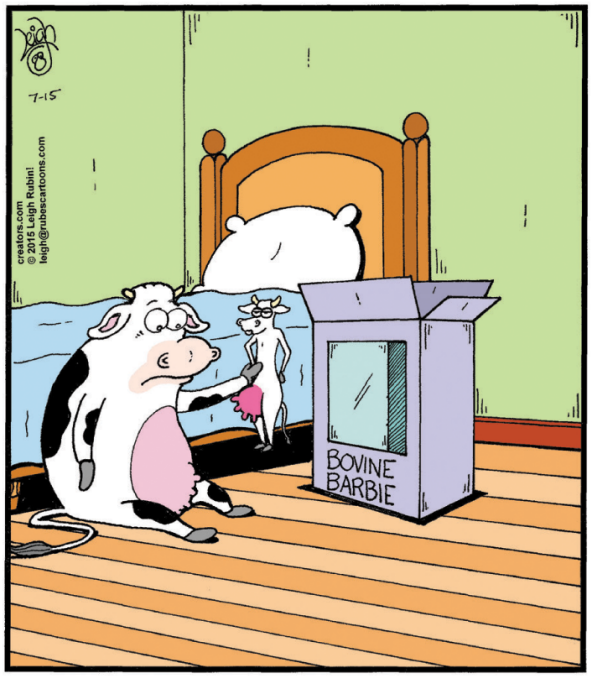
A distorted body image underlies anorexia.

At some point during their lifetime, about 2.6 million Americans (0.8 percent) have met the DSM-5-TR-defined criteria for anorexia, 2.6 million for bulimia, and 2.7 million for binge-eating disorder (Udo & Grilo, 2019). All three disorders can be deadly. They harm the body and mind, resulting in shorter life expectancy and greater risk of suicide and nonsuicidal self-injury (Cucchi et al., 2016; Fichter & Quadflieg, 2016; Mandelli et al., 2019).

Understanding Eating Disorders

Eating disorders are *not* (as some have speculated) a telltale sign of childhood sexual abuse (Smolak & Murnen, 2002; Stice, 2002). The

family environment may influence eating disorders in other ways, however. For example, the families of those with anorexia tend to be competitive, high-achieving, and protective (Ahrén et al., 2013; Berg et al., 2014; Yates, 1989, 1990).



Eating disorders share some commonalities with anxiety disorders (Schaumberg et al., 2021). Those with eating disorders often have low body satisfaction, set perfectionist standards, and ruminate about falling short of expectations and how others perceive them (Farstad et al., 2016; Smith et al., 2018; S. Wang et al., 2019). Some of these factors also predict teen boys' pursuit of unrealistic muscularity (Karazsia et al., 2017; Ricciardelli & McCabe, 2004).

Heredity also matters. Identical twins share these disorders more often than do fraternal twins—with 50 to 60 percent *heritability* for anorexia (Yilmaz et al., 2015). Scientists are searching for culprit genes. The largest study identified gene differences by comparing the genomes of nearly 17,000 people with anorexia with 56,000 others who did not have the disorder (Watson et al., 2019).

But eating disorders also have cultural and gender components. Ideal shapes vary across culture and time. Hungry people find larger bodies more attractive (Saxton et al., 2020). In countries with high poverty rates, plump may mean prosperity and thin may signal poverty or illness (Knickmeyer, 2001; Swami et al., 2010). Not so in high-income Western cultures. In one analysis of 222 studies, the rise in eating disorders in the last half of the twentieth century coincided with a

dramatic decline in Western women's body image (Feingold & Mazzella, 1998). Women have come to overestimate the female thinness that straight men prefer, while men overestimate the male muscularity that straight women prefer (Lei & Perrett, 2021).

Today's weight-obsessed culture—which sends the message that "fat is bad" in countless ways—motivates millions of women to diet constantly, and invites eating binges by pressuring women to live in a constant state of semistarvation. One former model recalled walking into a meeting with her agent, starving and with her organs failing due to anorexia (Carroll, 2013). Her agent's greeting: "Whatever you are doing, keep doing it." Women who view real and doctored images of unnaturally thin models and celebrities often feel ashamed, depressed, and dissatisfied with their own bodies—the very attitudes that predispose eating disorders (Bould et al., 2018; Tiggemann & Miller, 2010). Even ultrathin models do not reflect the impossible standard of the original Barbie doll, who had, when adjusted to a height of 5 feet 7 inches, a 32-inch bust, 16-inch waist, and 29-inch hips (in centimeters, 82–41–73) (Norton et al., 1996).

Leigh Rubes/Creators Syndicate, Inc.

"Up until that point, Bernice had never once had a problem with low self-esteem."

"Why do women have such low self-esteem? There are many complex psychological and societal reasons, by which I mean Barbie." — Humorist Dave Barry, 1999

Most people diagnosed with an eating disorder do improve. In one 22-year study, 2 in 3 women with anorexia nervosa or bulimia nervosa had recovered (Eddy et al., 2017). Prevention is also possible. Interactive programs that teach teen girls to accept their bodies have reduced the risk of eating disorders (Beintner et al., 2012; Melioli et al., 2016; Vocks et al., 2010). By combating cultural learning, those at risk may instead live long and healthy lives.

Retrieval Practice

RP-3 People with _____ _____ (anorexia nervosa/bulimia nervosa) continue to want to lose weight even when they are underweight. Those with _____ _____ (anorexia nervosa/bulimia nervosa) tend to have a weight that fluctuates within or above typical ranges.

Module 52: Dissociative, Personality, and Eating Disorders

Learning Objectives

Test Yourself Answer these repeated Learning Objective Questions on your own (before "showing" the answers here, or checking the answers in Appendix D) to improve your retention of the concepts (McDaniel et al., 2009, 2015).

LOQ 52-1: What are *dissociative disorders,* and why are they controversial?

LOQ 52-2: What are the three clusters of personality disorders? What behaviors and brain activity characterize antisocial personality

disorder?

LOQ 52-3: What are the three main eating disorders, and how do biological, psychological, and social-cultural influences make some people more vulnerable to them?

Terms and Concepts to Remember

Test Yourself Write down the definition in your own words, then check your answer.

dissociative disorders
dissociative identity disorder (DID)
personality disorders
antisocial personality disorder
anorexia nervosa
bulimia nervosa
binge-eating disorder

Module Test

Test Yourself Answer the following questions on your own first, then "show" the answers here, or check your answers in Appendix E.

1. Dissociative identity disorder is controversial because
    a. dissociation is quite rare.
    b. it was reported frequently in the 1920s but is rarely reported today.
    c. it is almost never reported outside North America.
    d. its symptoms are nearly identical to those of obsessive-compulsive disorder.

2. A personality disorder, such as antisocial personality, is characterized by
    a. depression.
    b. hallucinations.
    c. enduring inner experiences and behavior patterns that cause distress or impairment.
    d. an elevated level of autonomic nervous system arousal.

3. PET scans of murderers' brains have revealed
    a. higher-than-normal activation in the frontal lobes.
    b. lower-than-normal activation in the frontal lobes.
    c. more frontal lobe tissue than normal.
    d. no differences in brain structures or activity.

4. Which of the following statements is true of bulimia nervosa?
    a. People with bulimia continue to want to lose weight even when they are underweight.
    b. Bulimia is marked by weight fluctuations within or above typical ranges.

c. Those with bulimia do not follow food binges with compensating behaviors.
d. If one twin is diagnosed with bulimia, the chances of the other twin sharing the disorder are greater if they are fraternal rather than identical twins.

MODULE 53: Neurodevelopmental Disorders

Our thoughts and behaviors change as we grow older. For people with **neurodevelopmental disorders**, these typical changes are disrupted in childhood because of unusual features of the central nervous system. These disorders include *intellectual developmental disorders, autism spectrum disorder,* and *attention-deficit/hyperactivity disorder.*

Intellectual Developmental Disorder

LOQ 53-1

What is *intellectual developmental disorder?*

Intellectual developmental disorder is apparent before age 18, often with a known physical cause. *Down syndrome,* for example, is a disorder of varying intellectual and physical severity caused by an extra copy of chromosome 21 in the person's genetic makeup.

To be diagnosed with intellectual developmental disorder, a young person must meet two criteria. The first is low intellectual functioning as reflected in a low intelligence test score. Guidelines specify test score performance that is in the lowest 3 percent of the general

population, or about 70 or below (Schalock et al., 2010). The second criterion is that the person must have difficulty adapting to the normal demands of independent living, as expressed in three areas, or skills: *conceptual* (language, reading, and concepts of money, time, and number); *social* (interpersonal skills, being socially responsible, following basic rules and laws, avoiding being victimized); and *practical* (health and personal care, occupational skill, and travel). Intellectual developmental disorder results from a combination of genetic and environmental factors (Reichenberg et al., 2016).

Retrieval Practice

RP-1 What criteria must be met for someone to be diagnosed with intellectual developmental disorder?

ANSWERS IN APPENDIX E

Autism Spectrum Disorder

LOQ 53-2

What is *autism spectrum disorder?*

Autism spectrum disorder (ASD) is a cognitive and social-emotional disorder that is marked by social deficiencies and repetitive behaviors. Once believed to affect 1 in 2500 children (and referred to simply as

autism), ASD is now diagnosed in 1 in 38 children in South Korea, 1 in 54 in the United States, 1 in 62 in Canada, and 1 in 166 in Germany (CDC, 2020; Chiarotti & Venerosi, 2020). The increase in ASD diagnoses has been offset by a decrease in the number of children with a "cognitive disability" or "learning disability," which suggests a relabeling of children's disorders (Gernsbacher et al., 2005; Grinker, 2007; Shattuck, 2006).

martinedoucet/E+/Getty Images

Comforting connections In this shelter for battered and abandoned animals, children with a neurodevelopmental disorder learn to connect with the animals as a way of building their own strengths.

The underlying source of ASD's symptoms seems to be poor communication among brain regions that typically work together to let us take another's viewpoint. From age 2 months on, children typically spend more and more time looking into others' eyes; those who later develop ASD do so less and less (Baron-Cohen, 2017; Wang et al., 2020). Researchers are debating whether autistic people have an *impaired theory of mind* (Gernsbacher & Yergeau, 2019; Matthews &

Goldberg, 2018; Velikonja et al., 2019). Reading faces *(Is that face conveying a smile or a sneer?)* or even recognizing faces is often difficult for those with ASD (Griffin et al., 2021). Autistic people have difficulty inferring how others think differently than they do (Deschrijver & Palmer, 2020). For example, they may not appreciate that playmates and parents might view things differently, or understand that their teachers know more than they do (Boucher et al., 2012; Frith & Frith, 2001; Knutsen et al., 2015).

> **"I'm autistic, which means everyone around me has a disorder that makes them … creepily stare into my eyeballs."** — Facebook.com/autisticnotweird, 2020

A national survey of parents and school staff reported that 46 percent of adolescents with ASD had endured the taunts and torments of bullying—four times the 11 percent rate for other children (Sterzing et al., 2012). Children with ASD do make friends, but their peers often find such relationships emotionally unsatisfying (Mendelson et al., 2016). This helps explain why people with ASD have a quadrupled risk of experiencing depression in their lifetime (Hudson et al., 2019).

ASD has differing levels of severity. Some (those diagnosed with what used to be called *Asperger syndrome*) function at a high level, with average intelligence, often accompanied by exceptional skill or talent in a specific area. But those with more severe ASD may lack the motivation and ability to interact and communicate socially, and they tend to become distracted by irrelevant stimuli (Clements et al., 2018;

Remington et al., 2009). Those at the spectrum's most severe end struggle to use language.

> **"Autism makes my life difficult, but it also makes my life beautiful. When everything is more intense, then the everyday, the mundane, the typical, the normal—those things become outstanding."** — Erin McKinney, "The Best Way I Can Describe What It's Like to Have Autism," 2015

ASD gets diagnosed in about four boys for every girl, perhaps partly because girls may be more skilled in hiding ASD-related traits (CDC, 2020; Dean et al., 2017; Loomes et al., 2017). Psychologist Simon Baron-Cohen (2010), who has been knighted for his autism research, believes the imbalance is because boys—whether or not they have ASD—are "systemizers." They tend to understand things according to rules or laws, as in mathematical and mechanical systems. Girls, he contends, are more often predisposed to be "empathizers." They tend to excel at reading facial expressions, predicting what others will feel, and knowing what to do in social situations. Whether male or female, those with ASD are systemizers who have more difficulty reading facial expressions, intuitively knowing what others feel, and understanding how to have smooth social interactions (Greenberg et al., 2018; Velikonja et al., 2019). People working in STEM (science, technology, engineering, or mathematics) careers are also somewhat more likely than others to exhibit some ASD-like traits (Ruzich et al., 2015).

Justin Sellers/The Clarion Ledger/USA TODAY NETWORK/Imagn Content Services

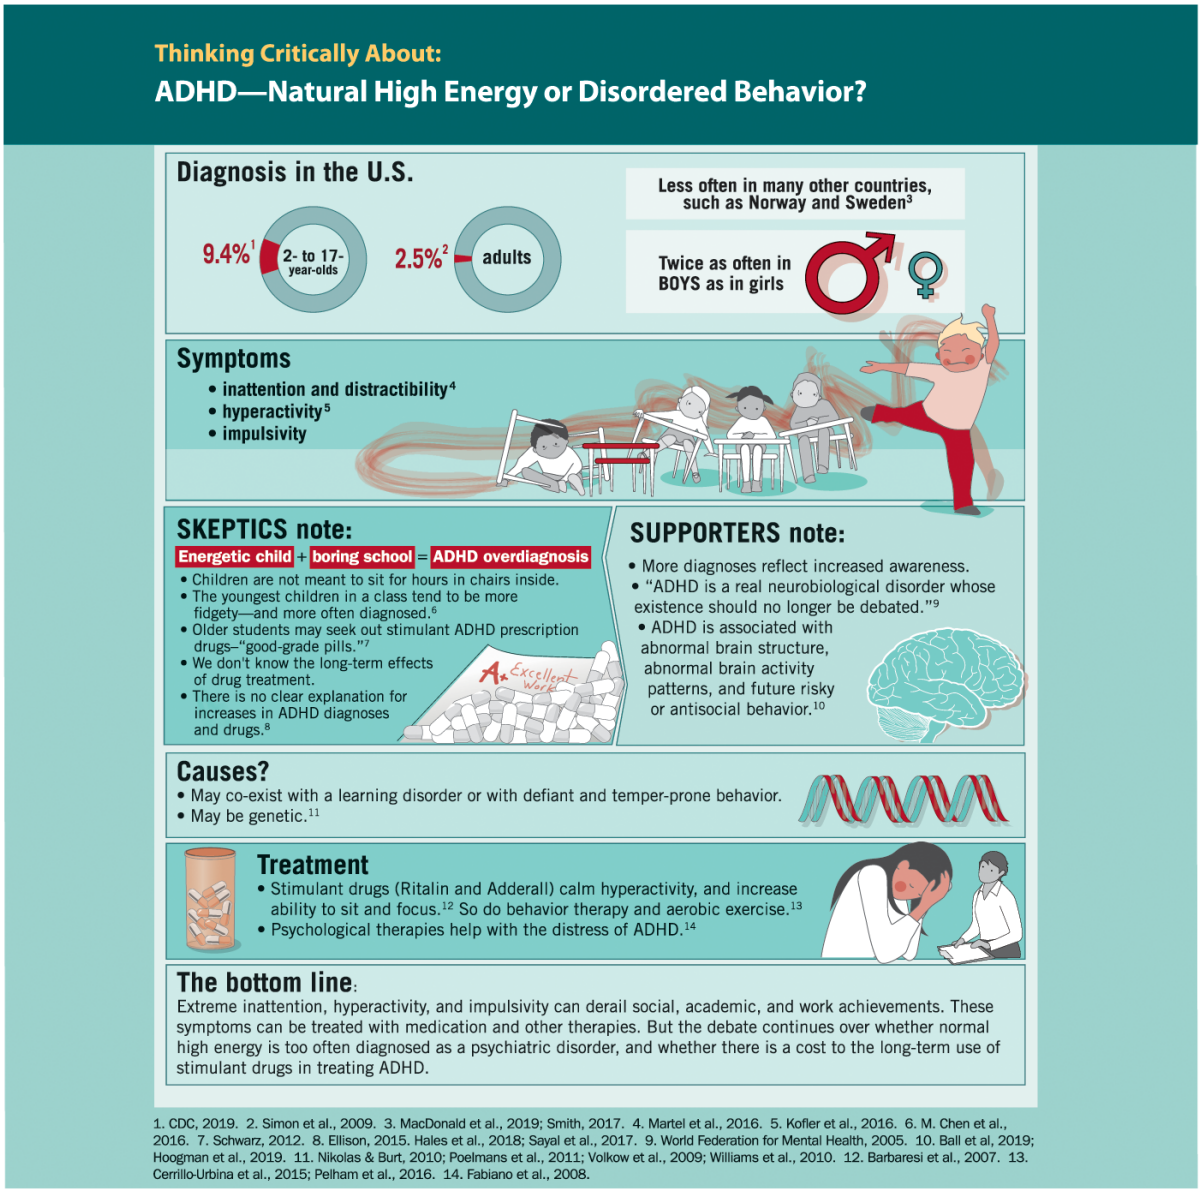
"Autism" case number 1 In 1943, Donald Gray Triplett, an "odd" child with unusual gifts and social limitations, was the first person to receive the diagnosis of "autism." (After a 2013 change in the diagnosis manual, his condition is now called *autism spectrum disorder.*) At age 82, Triplett—a retired bank teller who often played golf—was living independently in his family home and Mississippi town (Atlas, 2016). He is shown here (left) walking with his brother.

Biological factors contribute to ASD (Ecker et al., 2021; J. Zhou et al., 2019). Prenatal environment matters, especially when altered by maternal infection, psychiatric drug use, or stress hormones (NIH, 2013; Wang, 2014). Genes also matter. One five-nation study of 2 million people found the hereditability of ASD was near 80 percent (Bai et al., 2019). If one identical twin is diagnosed with ASD, the chances are near 9 in 10 that the co-twin will be as well, though such twins often differ in symptom severity (Castelbaum et al., 2020). No one "autism gene" accounts for the disorder. Rather, many genes—

with more than 400 identified so far—contribute (Krishnan et al., 2016; Yuen et al., 2016). Random genetic mutations in sperm cells may also play a role. As men age, these mutations become more frequent, which helps explain why a man over age 40 has a much higher risk of fathering a child with ASD than does a man under age 30 (Wu et al., 2017).

Researchers are also sleuthing ASD's telltale signs in the brain's structure. Several studies have revealed "underconnectivity"—fewer-than-normal fiber tracts connecting the front of the brain to the back (Picci et al., 2016). With underconnectivity, there is less of the whole-brain synchrony that, for example, integrates visual and emotional information. In children as young as 3 months, EEG-recorded brain activity can foretell ASD (Bosl et al., 2018).

Biology's role in ASD also appears in the brain's functioning. People without ASD often yawn after seeing others yawn. And as they view and imitate another's smiling or frowning, they feel something of what the other is feeling. Not so among those with ASD, who are less imitative and show less activity in brain areas involved in mirroring others' actions (Edwards, 2014; Yang & Hoffmann, 2015). When people with ASD watch another person's hand movements, for example, their brain displays less mirroring activity than is typical (Oberman & Ramachandran, 2007; Théoret et al., 2005). Scientists are exploring whether treatment with oxytocin, the hormone that promotes social bonding, might improve social understanding in those with ASD (Gordon et al., 2013; Lange & McDougle, 2013).



There is overwhelming evidence that childhood vaccinations, which—despite a fraudulent 1998 study claiming otherwise—*have no connection* to ASD. In fact, in one recent study following nearly 700,000 Danish children, those receiving the measles/mumps/rubella vaccine were slightly *less* likely to later be among the 6517 children diagnosed with ASD (Hviid et al., 2019). *The bottom line:* When deciding whether to vaccinate their children, parents should trust the scientific evidence. Childhood vaccinations do not increase the risk for ASD.

Attention-Deficit/Hyperactivity Disorder

For children who experience the challenging symptoms of **attention-deficit/hyperactivity disorder (ADHD)**, diagnosis and treatment can help (Kupfer, 2012; Maciejewski et al., 2016). The DSM has broadened the diagnostic criteria for this disorder, prompting critics to wonder whether the criteria are now too broad (Frances, 2013). Shall we say such a child is hyperactive—or energetic? Impulsive—or spontaneous? Excessively talkative—or excited? One 10-year study in Sweden found children's attentional behaviors unchanging, while national ADHD diagnoses increased fivefold (Rydell et al., 2018). (See Thinking Critically About: ADHD—Natural High Energy or Disordered Behavior?)

Preventing Psychological Disorders and Building Resilience

Psychologist Kay Redfield Jamison, a renowned expert on the emotional extremes of bipolar disorders, knows her subject firsthand. As she recalled in *An Unquiet Mind:*

> For as long as I can remember, I was frighteningly, although often wonderfully, beholden to moods. Intensely emotional as a child, mercurial as a young girl, first severely depressed as an adolescent, and then unrelentingly caught up in the cycles of manic-depressive illness [now known as *bipolar I disorder*] by the time I began my professional life, I became, both by necessity and intellectual inclination, a student of moods. (1995, pp. 4–5)

Jamison's life was blessed with times of intense sensitivity and passionate energy. But like her father's, it was also sometimes plagued by reckless spending, racing conversation, and sleeplessness, alternating with swings into "the blackest caves of the mind."

Then, "in the midst of utter confusion," she made a life-changing decision. Risking professional embarrassment, she made an appointment with a therapist, a psychiatrist she would visit weekly for years to come.

> He kept me alive a thousand times over. He saw me through madness, despair, wonderful and terrible love affairs, disillusionments and triumphs, recurrences of illness, an almost fatal suicide attempt, the death of a man I greatly loved, and the enormous pleasures and aggravations of my professional life…. He was very tough, as well as very kind, and even though he understood more than anyone how much I felt I was losing—in energy, vivacity, and originality—by taking medication, he never [lost] sight of the overall perspective of how costly, damaging, and life threatening my illness was…. Although I went to him to be treated for an illness, he taught me … the total beholdenness of brain to mind and mind to brain. (pp. 87–88)

Left: John Shearer/Getty Images; right: Kevin Winter/Getty Images for Variety

Value of therapy Actor Kerry Washington and singer Katy Perry have spoken publicly about the benefits of psychotherapy. “I’ve been going to therapy for about five years,” Perry said, “and I think it has really helped my mental health incredibly” (Chen, 2017).

These modules explore healing options available to therapists and those who seek their help. We begin by exploring and evaluating *psychotherapies* (Modules 54 and 55), and then focus on *biomedical therapies* and preventing disorders (Module 56).

MODULE 54: Introduction to Therapy and the Psychological Therapies

The long history of treating psychological disorders has included a bewildering mix of harsh and gentle methods. Would-be healers have cut holes in people's heads and restrained, bled, or "beat the devil" out of them. But they also have given warm baths and massages and placed people in sunny, serene environments. They have given them helpful drugs. And they have talked with them about childhood experiences, current feelings, and negative thoughts and behaviors.

The Granger Collection

The history of treatment Visitors to eighteenth-century psychiatric hospitals paid to gawk at patients, as though they were viewing zoo animals. William Hogarth's (1697–1764) painting captured one of these visits to London's St. Mary of Bethlehem hospital (commonly called Bedlam).

Reformers Philippe Pinel (1745–1826) and Dorothea Dix (1802–1887) pushed for gentler, more humane treatments and for constructing psychiatric hospitals. Since the 1950s, the introduction of effective drug therapies and community-based treatment programs has emptied most of those hospitals. Unfortunately, this *deinstitutionalization* has left many people with mental illness untreated, which has contributed to their increased homelessness and incarceration.

Macmillan Learning

Dorothea Dix "I … call your attention to the state of the Insane Persons confined within this Commonwealth, in cages" (*Memorial to the Legislature of Massachusetts*, 1843).

Treating Psychological Disorders

Learning Objective Question LOQ 54-1

How do *psychotherapy* and the *biomedical therapies* differ?

Modern Western therapies take two main forms.

- In **psychotherapy**, a trained therapist uses psychological techniques to help someone overcome difficulties and achieve personal growth. The therapist may explore a client's early relationships, encourage the client to adopt new ways of thinking, or coach the client in replacing old behaviors with new ones.
- **Biomedical therapy** offers medication or other biological treatments for psychological disorders. For example, a person with severe depression may receive antidepressants, electroconvulsive therapy (ECT), or brain stimulation.

Today, 1 in 5 Americans annually receives some form of mental health therapy (Olfson et al., 2019). The care provider's training and expertise, and the disorder itself, influence the choice of treatment. Psychotherapy and medication are often combined to treat psychological disorders. Kay Redfield Jamison received psychotherapy and took medications to control her dramatic mood swings.

Let's look first at some influential psychotherapy options. Each is built on one or more of psychology's major theories: psychodynamic,

humanistic, behavioral, and cognitive. Most of these techniques can be used one-on-one or in groups. Therapy often occurs in person, but people may also receive treatment by phone or online via *teletherapy*. Some therapists combine techniques. Indeed, many psychotherapists describe their approach as **eclectic** or integrative, using a blend of therapies.

Psychoanalysis and Psychodynamic Therapies

LOQ 54-2

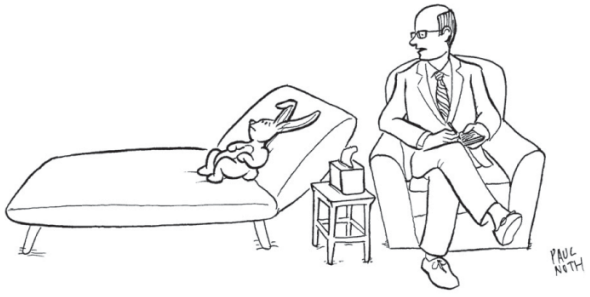
What are the goals and techniques of psychoanalysis, and how have they been adapted in psychodynamic therapy?

The first major psychological therapy was Sigmund Freud's **psychoanalysis.** Although few clinicians today practice therapy as Freud did, his work deserves discussion. It helped form the foundation for treating psychological disorders, and it continues to influence contemporary therapists working from the modern *psychodynamic* perspective.

The Goals of Psychoanalysis

Freud believed that in therapy, people could achieve healthier, less anxious living by releasing the energy they had previously devoted to *id-ego-superego* conflicts (Personality modules). Freud believed that

there are things we *repress*—things we do not want to know because they may cause distress, so we deny or avoid them. Psychoanalysis was Freud's method of helping people bring these repressed feelings into conscious awareness. By helping them reclaim their unconscious thoughts and feelings, and by giving them *insight* into the origins of their distress, the therapist *(analyst)* could help them reduce growth-impeding inner conflicts.



The Techniques of Psychoanalysis

Psychoanalytic theory emphasizes the power of early life experiences to mold the adult. It aims to unearth the past in the hope of loosening its hold on the present. After discarding hypnosis as an unreliable excavator, Freud turned to *free association*.

Imagine yourself as a patient using free association. You begin by relaxing, perhaps by lying on a couch. The psychoanalyst, who sits out of your line of vision, asks you to say aloud whatever comes to mind. At one moment, you're relating a childhood memory. At another, you're describing a disturbing dream and then what you ate for breakfast. Your thoughts may jump from one thing to the next. It sounds easy, but soon you notice how often you edit your thoughts as you speak. You pause for a second before uttering an embarrassing thought. You omit what seems trivial, irrelevant, or shameful. Sometimes your mind goes blank or you clutch up, unable to remember important details. You may joke or change the subject to something less threatening.

Freud thought that these mental blocks were signs of **resistance.** They hint that anxiety lurks and you are defending against uncomfortable material. An analyst would note your resistance and then provide insight into its meaning. If offered at the right moment, this **interpretation**—of, say, your reluctance to call or message your mother—may illuminate the underlying wishes, feelings, and conflicts you are avoiding. The analyst may also offer an explanation of how this resistance fits with other pieces of your psychological puzzle, including those based on analysis of your dream content.

Over many such sessions, your relationship patterns surface in your interaction with your analyst. You may find yourself experiencing strong positive or negative feelings for this confidant. The analyst may suggest you are **transferring** feelings, such as dependency or mingled love and anger, that you experienced in earlier relationships with family members or other important people. By exposing such feelings, you may gain insight into your current relationships.

Paul Noth/Cartoon Stock

"I'm more interested in hearing about the eggs you're hiding from yourself."

Today's therapists rarely offer Freud's traditional psychoanalysis. Much of its underlying theory is not supported by scientific research.

Analysts' interpretations cannot be proven or disproven. Psychoanalysis takes considerable time and money, often years of several sessions per week. Some of these problems have been addressed in the modern *psychodynamic perspective* that has evolved from psychoanalysis.

Retrieval Practice

RP-1 In psychoanalysis, when patients experience strong feelings for their analyst, this is called _____. Patients are said to demonstrate anxiety when they put up mental blocks around sensitive memories, indicating _____. The analyst will attempt to provide insight into the underlying anxiety by offering a(n) _____ of the mental blocks.

ANSWERS IN APPENDIX E

Psychodynamic Therapy

Although influenced by Freud's ideas, **psychodynamic therapists** don't talk much about symbolic id-ego-superego conflicts. Instead, they try to help people understand their current thoughts and feelings by focusing on important relationships and events, including early childhood experiences and the therapist-client relationship. "We can have loving feelings and hateful feelings toward the same person," observed psychodynamic therapist Jonathan Shedler (2009), and "we can desire something and also fear it." Client-therapist sessions occur weekly (rather than several times per week) and often for only a few weeks or months (rather than years). Clients meet with their therapist

in person, over the phone, or online. And in contrast to Freud's prescribing cocaine to his depressed patients(!), today's psychodynamic therapists might prescribe antidepressant drugs that have been researched, tested, and deemed safe for use (Driessen et al., 2020).

In their sessions, clients explore and gain perspective on defended-against thoughts and feelings. Therapist David Shapiro (1999, p. 8) illustrated this with the case of a young man who had told women he loved them but knew that he didn't. The client's explanation: They expected it, so he said it. But later, with his wife, who wished he would say that he loved her, he found himself unable—"I don't know why, but I can't."

> ***Therapist:*** Do you mean, then, that if you could, you would like to?
> ***Patient:*** Well, I don't know.… Maybe I can't say it because I'm not sure it's true. Maybe I don't love her.

Further interactions revealed that the client could not express real love because it would feel "mushy" and "soft" and therefore unmanly. He was "in conflict with himself, and … cut off from the nature of that conflict." Shapiro noted that with such patients, who are estranged from themselves, therapists using psychodynamic techniques "are in a position to introduce them to themselves. We can restore their awareness of their own wishes and feelings, and their awareness, as well, of their reactions against those wishes and feelings."

Humanistic Therapies

LOQ 54-3

What are the basic themes of humanistic therapy? What are the goals and techniques of Rogers' person-centered approach?

The *humanistic* perspective emphasizes people's innate goodness and potential for self-fulfillment. To this end, humanistic therapists help clients discover new insights. Indeed, because they share this goal, the psychodynamic and humanistic therapies are often referred to as **insight therapies.** But humanistic therapies differ from psychodynamic therapies in many ways, including their focus on three main ideas:

1. ***Growth.*** Humanistic therapists focus not on illness, but on helping people grow in self-awareness and self-acceptance. Thus, they call those in therapy "persons" or "clients" rather than "patients" (a change many other therapists have adopted).
2. ***The present.*** Humanistic psychologists believe the present and the future are more important than the past. Rather than uncovering hidden internal conflicts from the past, they encourage clients to take immediate responsibility for their current feelings and actions.
3. ***The conscious mind.*** Humanistic therapies focus on clients' conscious thoughts, which they believe are more important than unconscious thoughts.

These themes are present in the widely used **person-centered therapy**, a humanistic technique that Carl Rogers (1902–1987) developed. In this *nondirective* therapy, the client leads the discussion. The therapist listens, without judging or interpreting, and refrains from directing the client toward certain insights. Believing that most people possess the resources for growth, Rogers (1961, 1980) encouraged therapists to foster that growth through acceptance, genuineness, and empathy. By being *accepting*, therapists may help clients feel freer and more open to change. By being *genuine*, therapists hope to encourage clients to express their true feelings. By being *empathic*, therapists try to sense and reflect their clients' feelings, helping them experience a deeper self-understanding and self-acceptance (Hill & Nakayama, 2000). As Rogers (1980) explained nearly a half century ago,[1]

> Hearing has consequences. When I truly hear a person and the meanings that are important to him at that moment, hearing not simply his words, but him, and when I let him know that I have heard his own private personal meanings, many things happen. There is first of all a grateful look. He feels released. He wants to tell me more about his world. He surges forth in a new sense of freedom. He becomes more open to the process of change.
>
> I have often noticed that the more deeply I hear the meanings of the person, the more there is that happens. Almost always, when a person realizes he has been deeply heard, his eyes moisten. I think in some real sense he is weeping for joy. It is as though he were saying, "Thank God, somebody heard me. Someone knows what it's like to be me." (p. 10)

To Rogers, "hearing" was **active listening.** The therapist echoes, restates, and seeks clarification of what the person expresses (verbally or nonverbally). The therapist also acknowledges those expressed feelings. Active listening is now an accepted part of counseling practices in many schools, colleges, and clinics. Counselors listen attentively. They interrupt only to restate and confirm feelings, to accept what is being expressed, or to seek clarification. In the following brief excerpt, note how Rogers tried to provide a psychological mirror that would help the client see himself more clearly (Meador & Rogers, 1984, p. 167):

> ***Rogers:*** Feeling that now, hm? That you're just no good to yourself, no good to anybody. Never will be any good to anybody. Just that you're completely worthless, huh?—Those really are lousy feelings. Just feel that you're no good at all, hm?
> ***Client:*** Yeah. *(Muttering in low, discouraged voice)* That's what this guy I went to town with just the other day told me.
> ***Rogers:*** This guy that you went to town with really told you that you were no good? Is that what you're saying? Did I get that right?
> ***Client:*** M-hm.
> ***Rogers:*** I guess the meaning of that if I get it right is that here's somebody that meant something to you and what does he think of you? Why, he's told you that he thinks you're no good at all. And that just really knocks the props out from under you. *(Client weeps quietly.)* It just brings the tears. *(Silence of 20 seconds)*
> ***Client:*** *(Rather defiantly)* I don't care though.
> ***Rogers:*** You tell yourself you don't care at all, but somehow I guess some part of you cares because some part of you weeps over it.

Michael Rougier/The LIFE Picture Collection/Getty Images

Active listening Carl Rogers (right) empathized with a client during this group therapy session.

Can a therapist be a perfect mirror, without selecting and interpreting what is reflected? Rogers conceded that one cannot be *totally* nondirective. Nevertheless, he said, the therapist's most important contribution is to accept and understand the client. Given a nonjudgmental, grace-filled environment that provides **unconditional positive regard,** people may accept even their worst traits and still feel valued and whole.

How can we improve communication in our own relationships by listening more actively? Three Rogers-inspired hints may help:

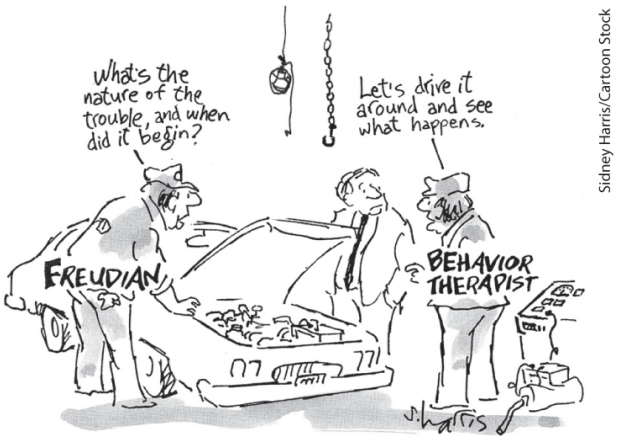
1. ***Paraphrase.*** Check your understanding by summarizing the person's words out loud, in your own words. "You felt

disappointed when your friend canceled your plans. Is that right?"

2. ***Invite clarification.*** "What might be an example of that?" may encourage the person to say more.
3. ***Reflect feelings.*** "It sounds frustrating" might mirror what you're sensing from the person's body language and intensity.

Ask Yourself

Think of your closest friends. Do they tend to express more empathy than those you feel less close to? How might *you* more deeply and actively listen to your friends?



Behavior Therapies

LOQ 54-4

How does the basic assumption of behavior therapy differ from the assumptions of psychodynamic and humanistic therapies? What classical conditioning techniques are used in exposure therapies and aversive conditioning?

The insight therapies assume that self-awareness and psychological well-being go hand in hand. For example, psychodynamic therapists expect people's problems to diminish as they gain insight into their unresolved and unconscious tensions. And humanistic therapists expect problems to diminish as people get in touch with their feelings. **Behavior therapists**, however, doubt the healing power of self-

awareness. Rather than delving deeply below the surface looking for inner causes, behavior therapists assume that problem behaviors *are* the problems. (You can become aware of why you are highly anxious during exams and still be anxious.) If specific phobias, sexual dysfunctions, or other maladaptive symptoms are learned behaviors, why not apply the learning principles of classical and operant conditioning to replace them with new, constructive behaviors?

Classical Conditioning Techniques

One cluster of behavior therapies derives from principles developed in Ivan Pavlov's early twentieth-century conditioning experiments. As Pavlov and others showed, we learn various behaviors and emotions through *classical conditioning* (Learning modules). If a dog attacks us, we may thereafter have a conditioned fear response when other dogs approach. If our fear generalizes and all dogs become conditioned stimuli, we may even develop a specific phobia for dogs.

Could maladaptive symptoms be examples of conditioned responses? If so, might reconditioning be a solution? Learning theorist O. H. Mowrer (1907–1982) thought so. He developed a successful conditioning therapy for chronic bed-wetting, using a liquid-sensitive pad connected to an alarm. If the sleeping child wets the bed pad, moisture triggers the alarm, waking the child. After several trials, the child associates bladder relaxation with waking. In three out of four cases, the treatment has been effective and the success has boosted the child's self-esteem (Christophersen & Edwards, 1992; Houts et al., 1994).

Can we unlearn fear responses, such as to public speaking or flying, through new conditioning? Many people have. An example: The fear of riding in an elevator is often a learned aversion to being in a confined space. **Counterconditioning**, such as with *exposure therapy*, pairs the trigger stimulus (in this case, the enclosed space of the elevator) with a new relaxation response that is incompatible with fear. Therapists use such techniques as slow and deep breathing or imagining peaceful images.

Retrieval Practice

RP-2 What might a psychodynamic therapist say about Mowrer's therapy for bed-wetting? How might a behavior therapist defend it?

ANSWERS IN APPENDIX E

Exposure Therapies

Picture this scene: Behavioral psychologist Mary Cover Jones is working with 3-year-old Peter, who is petrified of rabbits and other furry objects. To rid Peter of his fear, Jones plans to associate the fear-evoking rabbit with the pleasurable, relaxed response associated with eating a favorite snack. As Peter begins his midafternoon snack, she introduces a caged rabbit on the other side of the huge room. Peter, eagerly munching away on his crackers and drinking his milk, hardly notices. On succeeding days, she gradually moves the rabbit closer and closer. Within 2 months, Peter is holding the rabbit in his lap, even stroking it while he eats. Moreover, his fear of other furry objects subsides as well, having been *countered*, or replaced, by a relaxed state that cannot coexist with fear (Fisher, 1984; Jones, 1924).

Unfortunately for many who might have been helped by Jones' counterconditioning procedures, her story of Peter and the rabbit didn't become well-known when it was reported in 1924. It was more than 30 years before psychiatrist Joseph Wolpe (1958; Wolpe & Plaud, 1997) refined Jones' counterconditioning technique into the **exposure therapies** used today. These therapies, in a variety of ways, try to change people's reactions by repeatedly exposing them to stimuli that trigger unwanted reactions. We all experience this process in everyday life. A person moving to a new apartment may be annoyed by nearby loud traffic noise, but only for a while. With repeated exposure, the person adapts. So, too, with people who have fear reactions to specific events, such as people with PTSD (Thompson-Hollands et al., 2018). Exposed repeatedly to the situation that once petrified them, with

support from talk therapy, they can learn to react less anxiously (Holder et al., 2020). Exposure therapy is neither pleasant nor easy, so it helps to have supportive family and friends (Meis et al., 2019).

One exposure therapy used to treat specific phobias is **systematic desensitization.** You cannot simultaneously be anxious and relaxed. Therefore, if you can repeatedly relax when facing anxiety-provoking stimuli, you can gradually eliminate your anxiety. The trick is to proceed gradually. If you fear public speaking, a behavior therapist might first help you construct an *anxiety hierarchy*—a kind of ladder of speaking situations that trigger increasing anxiety levels. Yours might range from mildly anxiety-provoking situations (perhaps speaking up in a small group of friends) to panic-provoking situations (having to address a large audience).

Next, the therapist would train you in *progressive relaxation*. You would learn to release tension in one muscle group after another, until you achieve a comfortable, complete state of relaxation. Then the therapist might ask you to imagine, with your eyes closed, a mildly anxiety-arousing situation: You are having coffee with a group of friends and are trying to decide whether to speak up. If imagining the scene causes you to feel any anxiety, you are told to signal by raising your finger. Seeing the signal, the therapist will instruct you to switch off the mental image and go back to deep relaxation. This imagined scene is repeatedly paired with relaxation until you feel no trace of anxiety.

The therapist will then move to the next item in your anxiety hierarchy, again using relaxation techniques to desensitize you to each imagined situation. After several sessions, you move to actual situations and practice what you had only imagined before, beginning with relatively easy tasks (like speaking up among friends) and gradually moving to more anxiety-filled ones (like giving a public speech). Conquering your anxiety in an actual situation, not just in your imagination, will increase your self-confidence (Foa & Kozak, 1986; Williams, 1987). Eventually, you may even become a confident public speaker. Often people fear not just a situation, such as public speaking, but also being incapacitated by their own fear response. As their fear subsides, so also does their fear of the fear.

> **"According to most studies, people's number one fear is public speaking. Number two is death. Does that sound right? This means to the average person, if you go to a funeral, you are better off in the casket than doing the eulogy."** — Comedian Jerry Seinfeld

If anxiety-arousing situations (such as those that evoke fears of flying, heights, particular animals, and public speaking) are too expensive, difficult, or risky to re-create, the therapist may recommend **virtual reality exposure therapy**. Imagine donning a head-mounted display unit that projects a lifelike three-dimensional virtual world tailored to your particular fear (**FIGURE 54.1**). If you fear flying, for example, you could peer out of a simulated plane, feel the engine's vibrations, and hear it roar as the plane taxis down the runway and takes off. If you

fear social interactions, you could experience simulated stressful situations, such as entering a roomful of people. In controlled studies, people treated with virtual reality exposure therapy have experienced relief from real-life fear and social anxiety (Meyerbröker & Morina, 2021).

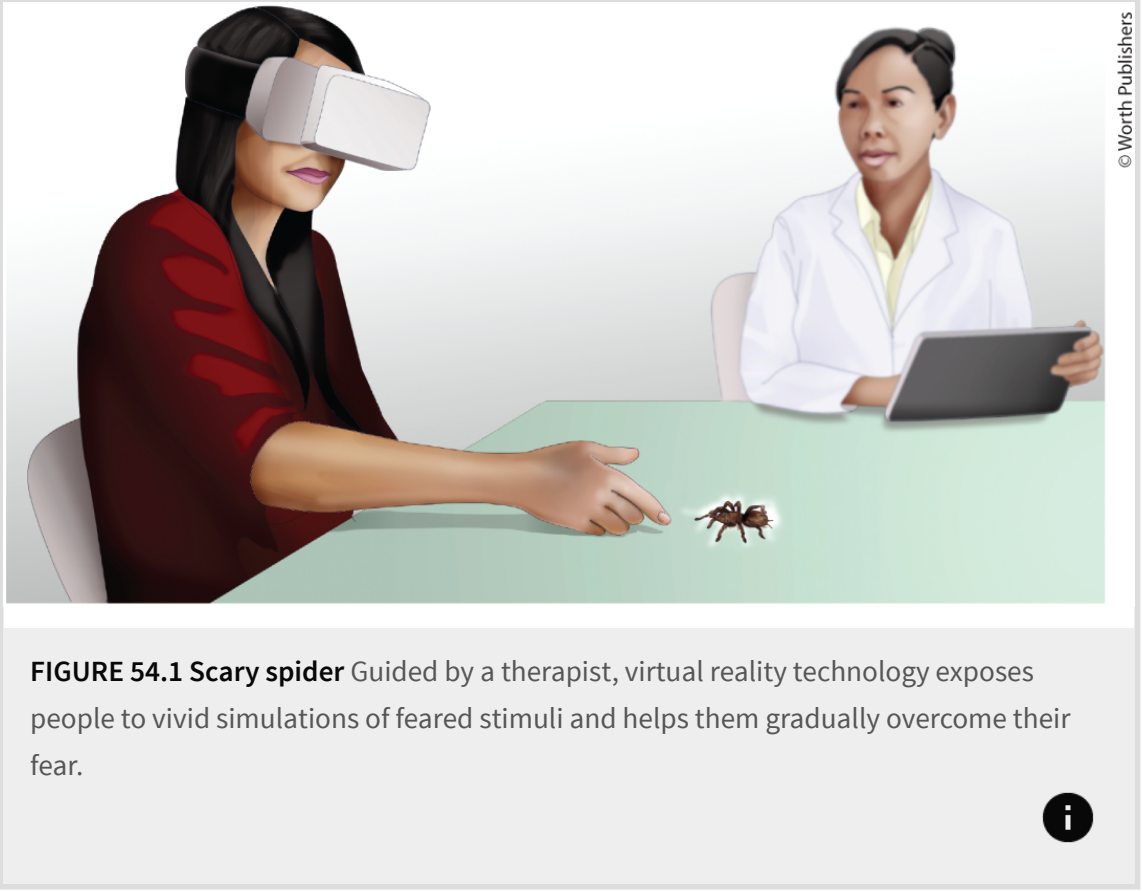


FIGURE 54.1 Scary spider Guided by a therapist, virtual reality technology exposes people to vivid simulations of feared stimuli and helps them gradually overcome their fear.

Aversive Conditioning

Exposure therapy helps you learn what you *should* do; it enables a more relaxed, positive response to an upsetting *harmless* stimulus. **Aversive conditioning** helps you learn what you *should not* do; it creates a negative (aversive) response to a *harmful* stimulus (such as

alcohol). The aversive conditioning procedure is simple: It associates the unwanted behavior with unpleasant feelings. To treat compulsive nail biting, the therapist may suggest painting the fingernails with a nasty-tasting nail polish (Brush, 2014). To treat alcohol use disorder, the therapist may offer the client appealing alcoholic drinks laced with a drug that produces severe nausea. If that therapy links alcohol with violent nausea, the person's reaction to alcohol may change from positive to negative (FIGURE 54.2).

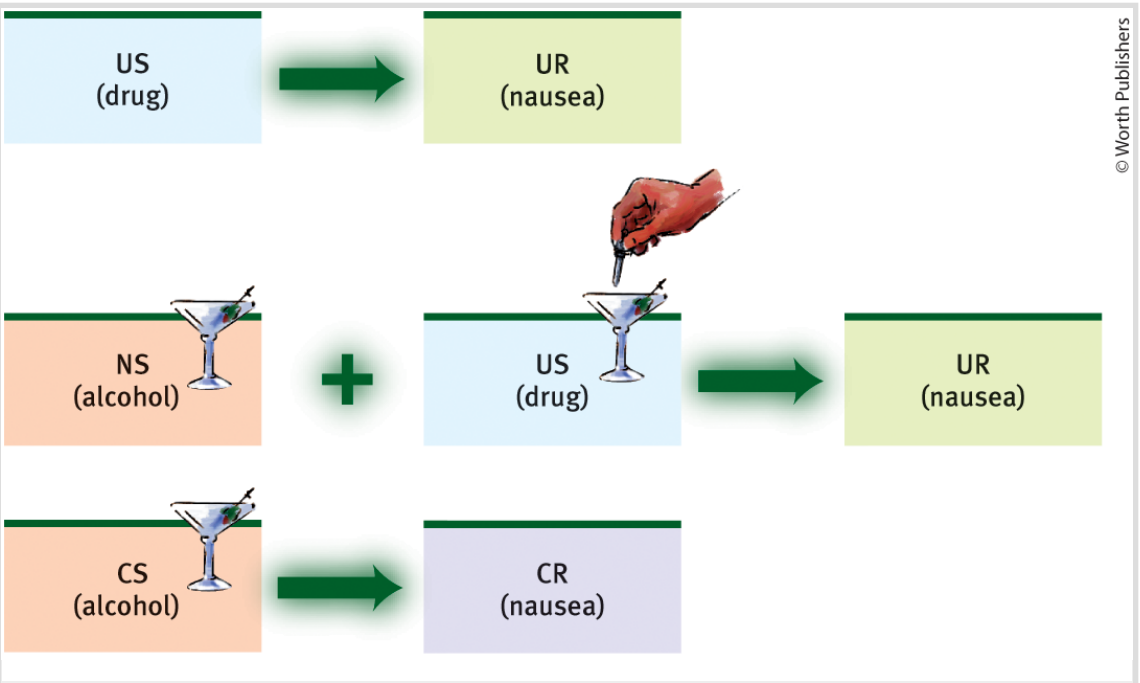

FIGURE 54.2 Aversion therapy for alcohol use disorder After repeatedly imbibing an alcoholic drink mixed with a drug that produces severe nausea, some people with a history of alcohol use disorder develop at least a temporary conditioned aversion to alcohol. (Remember: US is unconditioned stimulus, UR is unconditioned response, NS is neutral stimulus, CS is conditioned stimulus, and CR is conditioned response.)

Taste aversion learning has been a successful alternative to killing predators in some animal protection programs (Dingfelder, 2010; Garcia & Gustavson, 1997). After being sickened by eating a tainted sheep, wolves may later avoid sheep. Does aversive conditioning also transform humans' reactions to alcohol? In the short run it may. In one classic study, 685 participants with alcohol use disorder completed an aversion therapy program (Wiens & Menustik, 1983). Over the next year, they returned for several booster treatments that paired alcohol with sickness. At the end of that year, 63 percent were not drinking alcohol. But the effects diminished when the boosters stopped: After three years, only 33 percent were alcohol free.

In therapy, as in research, cognition influences conditioning. People know that outside the therapist's office they can drink without fear of nausea. This ability to discriminate between the therapy situation and all others can limit aversive conditioning's effectiveness. Thus, therapists often combine aversive conditioning with other treatments.

Operant Conditioning Techniques

LOQ 54-5

What is the main premise of behavior therapy based on operant conditioning principles, and what are the views of its proponents and critics?

If you have learned to swim, you learned to hold your breath with your head under water, to pull your body through the water, to bring your

face above water to breathe, and perhaps even to dive safely. Operant conditioning shaped your swimming. You were reinforced for safe, effective behaviors. And you were naturally punished, as when you swallowed water, for improper swimming behaviors.

Consequences strongly influence our voluntary behaviors. Knowing this basic principle of operant conditioning, behavior therapists can apply *behavior modification*. They reinforce desirable behaviors, and they fail to reinforce—or sometimes punish—undesirable behaviors.

Using operant conditioning to solve specific behavior problems has raised hopes for some seemingly hopeless cases. Children with intellectual developmental disorder have been taught to care for themselves. Socially withdrawn children with autism spectrum disorder (ASD) have learned to interact. People with schizophrenia have been helped to behave more rationally. In such cases, therapists use positive reinforcers to *shape* behavior. In a step-by-step manner, they reward closer and closer approximations of the desired behavior.

Rewards used to modify behavior vary. For some people, the reinforcing power of attention or praise is sufficient. Others require concrete rewards, such as food. In institutional settings, therapists may create a **token economy**. When people display a desired behavior, such as getting out of bed, washing, dressing, eating, talking coherently, cleaning up their rooms, or playing cooperatively, they receive a token or plastic coin. Later, they can exchange a number of these tokens for rewards, such as candy, TV time, day trips, or better

living quarters. Token economies have proven successful in a number of settings, including group homes, classrooms, and correctional institutions, and among people with various disabilities (Matson & Boisjoli, 2009). They have been widely used for children with ADHD, ASD, and other behavioral difficulties (Coehlo et al., 2015; Gilley & Ringdahl, 2014; Kazdin, 1982).

John D. Buffington/DigitalVision/Getty Images

Behavior modification critics express two concerns:

- ***How durable are the behaviors?*** Will people become so dependent on extrinsic rewards that the desired behaviors will stop when reinforcers stop? Behavior modification advocates believe the behaviors will endure if therapists wean people from the tokens by shifting them toward other, real-life rewards, such as social approval. Further, they point out, the desired behaviors themselves can be rewarding. As people become more socially competent, the intrinsic satisfaction of social interaction may sustain the behaviors.
- ***Is it right for one human to control another's behavior?*** Those who set up token economies deprive people of something they

desire and decide which behaviors to reinforce. To critics, this whole process feels authoritarian. Advocates reply that control already exists: People's destructive behavior patterns are being maintained and perpetuated by natural reinforcers and punishers in their environments. Isn't using positive rewards to reinforce adaptive behavior more humane than institutionalizing or punishing people? Advocates also argue that the right to effective treatment and an improved life justifies temporary deprivation.

Ask Yourself

What is your judgment of behavior modification techniques, such as those used in token economies? Do you agree or disagree with this approach?

Retrieval Practice

RP-3 What are the *insight therapies,* and how do they differ from behavior therapies?

RP-4 Some maladaptive behaviors are learned. What hope does this fact provide?

RP-5 Exposure therapies and aversive conditioning are applications of _____ conditioning. Token economies are an application of _____ conditioning.

ANSWERS IN APPENDIX E

Cognitive Therapies

LOQ 54-6

What are the goals and techniques of the cognitive therapies and of cognitive-behavioral therapy?

People with specific fears and problem behaviors may respond to behavior therapy. But how might behavior therapists modify the wide assortment of behaviors that accompany depressive disorders? Or treat people with generalized anxiety disorder, where unfocused anxiety doesn't lend itself to a neat list of anxiety-triggering situations? The *cognitive revolution* that has profoundly changed other areas of psychology since the 1960s has also influenced therapy.

> **"You have power over your mind."** — Marcus Aurelius (121–180 C.E.), *Meditations*

The **cognitive therapies** assume that our *thinking* colors our *feelings* (**FIGURE 54.3**). Between an event and our response lies the mind. Anxiety, for example, can arise from an "attention bias to threat" (MacLeod & Clarke, 2015). Self-blaming and overgeneralized explanations of bad events feed depression. If depressed, we may interpret a suggestion as criticism, disagreement as dislike, praise as flattery, friendliness as pity. Dwelling on such thoughts (ruminating) sustains or worsens negative thinking.

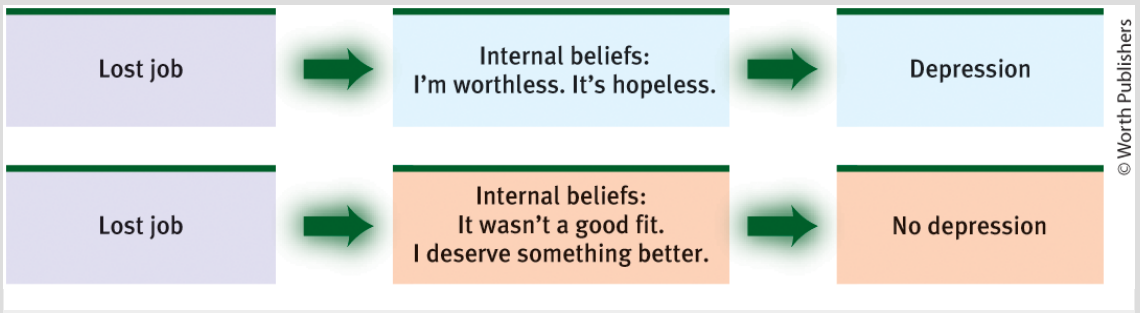

FIGURE 54.3 A cognitive perspective on psychological disorders The person's emotional reactions are produced not directly by the event, but by the person's thoughts in response to the event.

If feeling depressed is sometimes nature's way of getting us to slow down and solve a problem, cognitive therapies may speed up that problem solving (Hollon, 2020). Cognitive therapies help people change their mind with new, more constructive ways of perceiving and interpreting events (Burns, 1981; Persons, 2016; Schmidt et al., 2019).

> **"Life does not consist mainly, or even largely, of facts and happenings. It consists mainly of the storm of thoughts that are forever blowing through one's head."** — Writer Mark Twain, *Autobiography, Volume 1,* 1924

Beck's Cognitive Therapy

In the late 1960s, a woman left a party early. Things had not gone well. She felt disconnected from the other partygoers and assumed no one liked her. A few days later, she visited cognitive therapist Aaron Beck.

Rather than go down the traditional path to her childhood, Beck questioned her current thinking. After she then listed a dozen people who *did* like her, Beck realized that challenging people's automatic negative thoughts could be therapeutic. After trying this approach with other clients, he developed cognitive therapy, which assumes that changing people's thinking can change their functioning (Spiegel, 2015).

Macmillan Learning

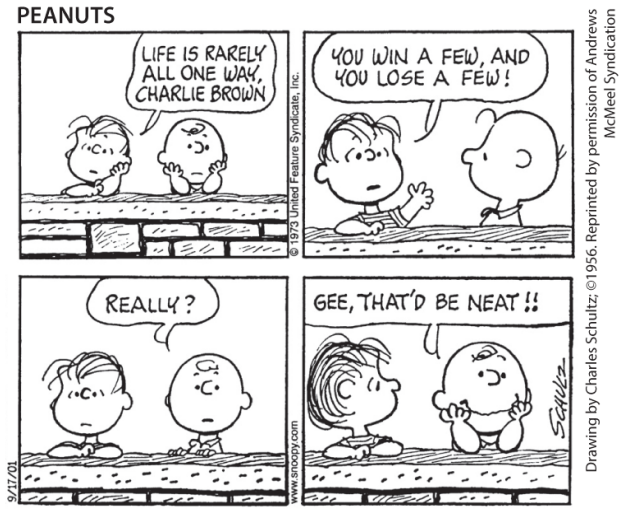
Aaron Beck (1921–2021) "Cognitive therapy seeks to alleviate psychological stresses by correcting faulty conceptions and beliefs. By correcting erroneous beliefs we can lower excessive reactions" (Beck, 1978).

People with depression, Beck found, often reported dreams with negative themes of loss, rejection, and abandonment. These themes extended into their waking thoughts, and even into therapy, as clients

recalled and rehearsed their failings and worst impulses (Kelly, 2000). Beck and his colleagues (1979) used cognitive therapy to reverse clients' negativity about themselves, their situations, and their futures. With this technique, gentle questioning seeks to reveal irrational thinking, and then to persuade people to remove the dark glasses through which they view life (Beck et al., 1979):

> ***Client:*** I agree with the descriptions of me but I guess I don't agree that the way I think makes me depressed.
> ***Beck:*** How do you understand it?
> ***Client:*** I get depressed when things go wrong. Like when I fail a test.
> ***Beck:*** How can failing a test make you depressed?
> ***Client:*** Well, if I fail I'll never get into law school.
> ***Beck:*** So failing the test means a lot to you. But if failing a test could drive people into clinical depression, wouldn't you expect everyone who failed the test to have a depression? … Did everyone who failed get depressed enough to require treatment?
> ***Client:*** No, but it depends on how important the test was to the person.
> ***Beck:*** Right, and who decides the importance?
> ***Client:*** I do.
> ***Beck:*** And so, what we have to examine is your way of viewing the test (or the way that you think about the test) and how it affects your chances of getting into law school. Do you agree?
> ***Client:*** Right.
> ***Beck:*** Do you agree that the way you interpret the results of the test will affect you? You might feel depressed, you might have trouble sleeping, not feel like eating, and you might even wonder if you should drop out of the course.
> ***Client:*** I have been thinking that I wasn't going to make it.
> ***Beck:*** Now what did failing mean?
> ***Client:*** *(tearful)* That I couldn't get into law school.
> ***Beck:*** And what does that mean to you?

Client: That I'm just not smart enough.



Beck: Anything else?

Client: That I can never be happy.

Beck: And how do these thoughts make you feel?

Client: Very unhappy.

Beck: So it is the meaning of failing a test that makes you very unhappy. In fact, believing that you can never be happy is a powerful factor in producing unhappiness. So, you get yourself into a trap—by definition, failure to get into law school equals "I can never be happy." (pp. 145–146)

We often think in words. Therefore, getting people to change what they say to themselves is an effective way to change their thinking. Perhaps you can identify with the anxious students who, before an exam, make matters worse with self-defeating thoughts: "This exam's going to be impossible. All these other students are so confident. I didn't study hard enough. I'll probably forget everything."

Psychologists call this sort of relentless, overgeneralized, self-blaming behavior *catastrophizing*.

To change such negative *self-talk,* cognitive therapists have offered *stress inoculation training*: teaching people to restructure their thinking in stressful situations (Meichenbaum, 1977, 1985). Sometimes it may be enough simply to say more positive things to yourself: "Relax. The exam may be hard, but it will be hard for everyone else, too. I studied harder than most people. Besides, I don't need a perfect score to get a good grade." After learning to "talk back" to negative thoughts, depression-prone children, teens, and college students have shown a greatly reduced rate of future depression (Reivich et al., 2013; Seligman et al., 2009). Ditto for anxiety (Krueze et al., 2018). To a large extent, it *is* the thought that counts. For a sampling of commonly used cognitive therapy techniques, see **TABLE 54.1**.

TABLE 54.1 Selected Cognitive Therapy Techniques

Aim of Technique	Technique	Therapists' Directives
Reveal beliefs	Question your interpretations	Explore your beliefs, revealing faulty assumptions such as "I must be liked by everyone."
	Rank thoughts and emotions	Gain perspective by ranking your thoughts and emotions from mildly to extremely upsetting.

Test beliefs	Examine consequences	Explore difficult situations, assessing possible consequences and challenging faulty reasoning.
	Decatastrophize thinking	Work through the actual worst-case consequences of the situation you face (it is often not as bad as imagined). Then determine how to cope with the real situation you face.
Change beliefs	Take appropriate responsibility	Challenge total self-blame and negative thinking, noting aspects for which you may be truly responsible, as well as aspects that aren't your responsibility.
	Resist extremes	Develop new ways of thinking and feeling to replace maladaptive habits. For example, change from thinking "I am a total failure" to "I got a failing grade on that paper, and I can make these changes to succeed next time."

It's not just depressed people who can benefit from positive self-talk. We all talk to ourselves (thinking "I wish I hadn't said that," for example, can protect us from repeating the blunder). The findings of nearly three dozen sport psychology studies show that self-talk interventions can even enhance the learning of athletic skills (Hatzigeorgiadis et al., 2011). Novice basketball players may be trained to think "focus" and "follow through," swimmers to think "high elbow," and tennis players to think "look at the ball." People anxious about public speaking have grown in confidence if asked to recall a speaking success and then asked this: "Explain WHY you were able to achieve such a successful performance" (Zunick et al., 2015).

Ask Yourself

Have you ever struggled to reach a goal at school or work because of your own self-defeating thoughts? How could you challenge those thoughts?

Cognitive-Behavioral Therapy

"The trouble with most therapy," said therapist Albert Ellis (1913–2007), "is that it helps you to feel better. But you don't get better. You have to back it up with action, action, action." **Cognitive-behavioral therapy (CBT)** takes a combined approach to treating depression, anxiety, and many other disorders. This widely practiced *integrative* therapy aims to alter not only the way people *think* but also the way they *act*. Like other cognitive therapies, CBT seeks to make people aware of their irrational negative thinking and to replace it with new ways of thinking. And like other behavior therapies, it trains people to *practice* the more positive approach in everyday settings.

Anxiety, depressive, and bipolar disorders share a common problem: unhealthy emotion regulation (Aldao & Nolen-Hoeksema, 2010; Gruber et al., 2011; Szkodny et al., 2014). An effective CBT program for these emotional disorders trains people both to replace their catastrophizing *thinking* with more realistic appraisals, and, as homework, to practice *behaviors* that are incompatible with their problem (Kazantzis et al., 2010; Moses & Barlow, 2006). A person might record daily situations associated with negative and positive

emotions, and engage more in activities that increase well-being. Those who fear social situations might learn to restrain the negative thoughts surrounding their social anxiety and practice approaching people.

arturs foto/iStock/Getty Images

CBT for eating disorders aided by journaling
Cognitive-behavioral therapists guide people with eating disorders toward new ways of explaining their good and bad food-related experiences (Linardon et al., 2017). By recording positive events and how she has enabled them, this woman may become more aware of her self-control and more optimistic.

CBT is an effective treatment for people with obsessive-compulsive and related disorders (Öst et al., 2015; Tolin et al., 2019). In one classic study, people learned to prevent their compulsive behaviors by relabeling their obsessive thoughts (Schwartz et al., 1996). Feeling the urge to wash their hands again, they would tell themselves, “I’m having a compulsive urge.” They would explain to themselves that the hand-washing urge was a result of their brain’s abnormal activity,

which they had previously viewed in PET scans. Then, instead of giving in, they would spend 15 minutes in an enjoyable, alternative behavior—practicing an instrument, taking a walk, gardening. This helped "unstick" the brain by shifting attention and engaging other brain areas. For two or three months, the weekly therapy sessions continued, with relabeling and refocusing practice at home. By the study's end, most participants' symptoms had diminished and their PET scans revealed normalized brain activity. Many other studies confirm CBT's effectiveness for treating other disorders, such as PTSD and alcohol or other substance use disorders (Lewis et al., 2020; Magill et al., 2020).

CBT variations have added new angles to treat clients' thinking and behavior. For example, *dialectical behavior therapy (DBT)* helps change harmful and even suicidal behavior patterns (Linehan, 2020; McCauley et al., 2018). *Dialectical* means "opposing," and this therapy attempts to make peace between two opposing forces—acceptance and change. Therapists create an accepting and encouraging environment, helping clients feel they have an ally who will offer them constructive feedback and guidance. In individual sessions, clients learn new ways of thinking that help them tolerate distress and regulate their emotions. They may also receive training in social skills and in *mindfulness meditation,* which helps alleviate depression and anxiety (Haller et al., 2021; Wielgosz et al., 2019). Group training sessions offer additional opportunities to practice new skills in a social context, with further practice as homework.

Acceptance and commitment therapy (ACT) helps clients learn to *accept* their feelings and *commit* to actions that are more consistent with their life values (Hayes et al., 2009). ACT effectively treats depression and anxiety, and even chronic pain (Bai et al., 2020; van Agteren et al., 2021).

RP-8 What is *cognitive-behavioral therapy,* and what sorts of problems does this therapy best address?

ANSWERS IN APPENDIX E

Group Therapy, Couples Therapy, and Family Therapy

LOQ 54-7

What are the aims and benefits of group therapy, couples therapy, and family therapy?

Group Therapy

Except for traditional psychoanalysis, most therapies may also occur in small groups. **Group therapy** does not provide the same degree of therapist involvement with each client. However, it offers other benefits:

- ***It saves therapists' time and clients' money,*** and often is no less effective than individual therapy (Burlingame et al., 2016).
- ***It offers a social laboratory for exploring social behaviors and developing social skills.*** Therapists frequently suggest group therapy for people experiencing frequent conflicts or whose behavior distresses others. The therapist guides people's interactions as they discuss issues and try out new behaviors.
- ***It enables people to see that others share their problems.*** It can be a relief to discover that others have experienced similar stressors, troublesome feelings, and behaviors (Rahman et al., 2019).
- ***It helps clients understand their feelings around others.*** Sometimes our most difficult feelings happen in our close relationships. Couples therapy helps people understand and work through unhealthy emotions and communication patterns with their partners.
- ***It provides feedback as clients try out new ways of behaving.*** Hearing that you look or sound poised, even though you feel anxious and self-conscious, can be very reassuring.

*"We are communicating better,
but we are still not out of the woods."*

Family Therapy

One special type of group interaction, **family therapy**, assumes that no person is an island (Baucom & Crenshaw, 2019). We live and grow in relation to others, especially our family. We struggle to differentiate ourselves from our families, but we also need to connect with them emotionally. These two opposing tendencies can create stress for both the individual and the family.

Family therapists view families as systems, in which each person's actions trigger reactions from others. A child's rebellion, for example, affects and is affected by other family tensions. Therapists are often successful in helping family members identify their roles within the family's social system, improve communication, and discover new ways of preventing or resolving conflicts (Hazelrigg et al., 1987;

Shadish et al., 1993). Family-focused treatments focus on understanding and building healthier and more supportive family interactions, especially for younger family members who have mood difficulties (Miklowitz & Chung, 2016).

Left: Hispanolistic/E+/Getty Images; right: Prostock-Studio/iStock/Getty Images

Group and couples therapy People in group therapy may find comfort in knowing others share their challenges. *Couples therapy* focuses on how romantic partners' ways of relating to each other create problems, and how they might change their interactions. Couples therapy often increases emotional intimacy, healthy communication, and relationship satisfaction (Roddy et al., 2020).

Self-Help Groups

More than 100 million in the United States have belonged to religious, special-interest, or support groups that meet regularly—with 9 in 10 reporting that group members "support each other emotionally" (Gallup, 1994). Self-help groups often provide support to people who struggle to find it elsewhere (Dingle et al., 2021). One analysis of more than 14,000 self-help groups reported that most focus on stigmatized, hard-to-discuss problems (Davison et al., 2000).

Many self-help groups use a 12-step program modeled on that of Alcoholics Anonymous (AA), the grandparent of support groups. Such a program asks members to admit their powerlessness, to seek help from a higher power and from one another, and (the twelfth step) to take the message to others in need of it (Galanter, 2016). Studies of 12-step programs such as AA have found that they help reduce alcohol use disorder at rates comparable to other treatment interventions (Ferri et al., 2006; Moos & Moos, 2005). An 8-year, $27 million investigation found that AA participants reduced their drinking sharply, as did those assigned to CBT or an alternative therapy (Project Match, 1997). The more meetings AA members attend, the greater their alcohol abstinence (Moos & Moos, 2006). Those whose personal stories include a "redemptive narrative"—who see something good as having come from their struggles—more often sustain sobriety (Dunlop & Tracy, 2013).

> With close to 2 million members in 180 countries, AA is said to be "the largest organization on Earth that nobody wanted to join" (Finlay, 2000).

In an individualist age, with more and more people living alone or feeling isolated, the popularity of support groups—for the addicted, the bereaved, the divorced, or simply those seeking fellowship and growth—may reflect a longing for community and connectedness.

***

For a synopsis of these modern psychotherapies, see TABLE 54.2.

TABLE 54.2 Comparing Modern Psychotherapies

Therapy	Targeted Problem	Therapy Aim	Therapy Technique
Psychodynamic	Unconscious conflicts from childhood experiences	Reduce anxiety through self-insight.	Interpret clients' memories, dreams, and feelings.
Person-centered	Barriers to self-understanding and self-acceptance	Enable growth via unconditional positive regard, acceptance, genuineness, and empathy.	Listen actively and reflect clients' feelings.
Behavior	Dysfunctional behaviors	Learn adaptive behaviors; extinguish problem behaviors.	Use classical conditioning (via exposure or aversion therapy) or operant conditioning (as in token economies).
Cognitive	Negative, self-defeating thinking	Promote healthier thinking and self-talk.	Train people to dispute their negative thoughts and attributions.
Cognitive-behavioral	Self-harmful thoughts and behaviors	Promote healthier thinking and adaptive behaviors.	Train people to counter self-harmful thoughts and to act out their new ways of thinking.
Group, couples, and family	Stressful relationships	Heal relationships.	Develop an understanding of family and other social systems, explore roles, and improve communication.

family therapy

Module Test

Test Yourself Answer the following questions on your own first, then "show" the answers here, or check your answers in Appendix E.

1. A therapist who helps clients search for the unconscious roots of their problem and offers interpretations of their behaviors, feelings, and dreams is drawing from
   a. psychoanalysis.
   b. humanistic therapies.
   c. person-centered therapy.
   d. behavior therapy.

2. _____ therapies are designed to help individuals discover the unconscious thoughts and feelings that guide

their motivation and behavior.

3. Compared with psychoanalysts, humanistic therapists are more likely to emphasize
   a. hidden or repressed feelings.
   b. childhood experiences.
   c. psychological disorders.
   d. self-fulfillment and growth.

4. A therapist who restates and clarifies the client's statements is practicing the technique of _____ _____.

5. The goal of behavior therapy is to
   a. identify and treat the underlying causes of the problem.
   b. improve learning and insight.
   c. eliminate the unwanted behavior.
   d. improve communication and social sensitivity.

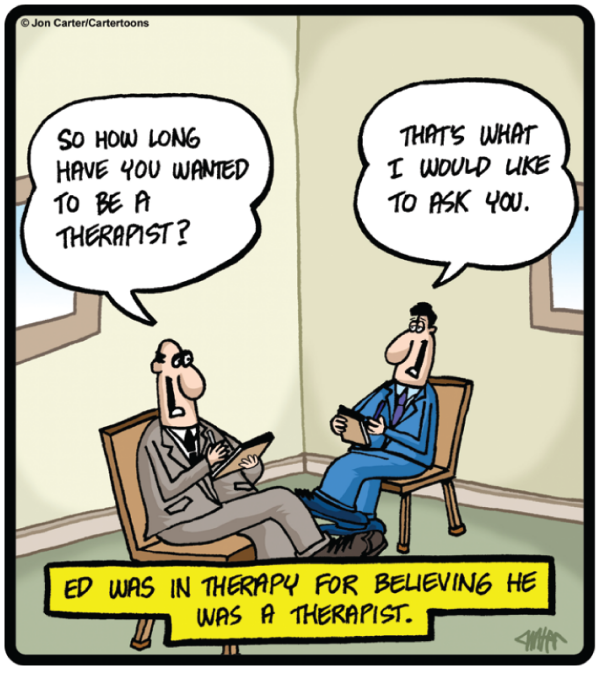
6. Behavior therapies often use _____ techniques, such as systematic desensitization and aversive conditioning, to encourage clients to produce new responses to old stimuli.

7. The technique of _____ _____ teaches people to relax in the presence of progressively more anxiety-provoking stimuli.

8. After a near-fatal car accident, Rico developed such an intense fear of driving on the highway that he takes lengthy alternative routes to work each day. Which psychological

therapy might best help Rico overcome his specific phobia, and why?

9. At a treatment center, people who display a desired behavior receive coins that they can later exchange for other rewards. This is an example of a(n) _____ _____.



10. Cognitive therapy has been especially effective in treating
    a. nail biting.
    b. specific phobias.
    c. alcohol use disorder.
    d. depressive disorders.

11. _____-_____ therapy helps people to change their self-defeating ways of thinking and to act out those changes in their daily behavior.

12. In family therapy, the therapist assumes that
    a. only one family member needs to change.
    b. each person's actions trigger reactions from other family members.
    c. dysfunctional family behaviors are based largely on genetic factors.
    d. therapy is most effective when clients are treated apart from the family unit.

MODULE 55: Evaluating Psychotherapies

Many people presume psychotherapy's effectiveness. "Seek counseling" or "Ask your partner to find a therapist," advice columnists often urge. Before 1950, psychiatrists were the primary providers of mental health care. Today's providers include clinical and counseling psychologists; clinical social workers; pastoral, marital, abuse, and school counselors; and psychiatric nurses. With such an enormous outlay of time as well as money and effort, it is important to ask: Are the millions of people worldwide justified in placing their hopes in psychotherapy?

Is Psychotherapy Effective?

LOQ 55-1

Does psychotherapy work? How can we know?

The question, though simply put, is not simply answered. If an infection quickly clears, we may assume an antibiotic has been effective. But how can we assess psychotherapy's effectiveness? By how we feel about our progress? By how our therapist feels about it? By how our friends and family feel about it? By how our behavior has changed?

Client Perceptions

If client testimonials were the only measuring stick, we could strongly affirm psychotherapy's effectiveness. Consider one early survey of 2900 *Consumer Reports* readers who related their experiences with mental health professionals (*Consumer Reports*, 1995; Kotkin et al., 1996; Seligman, 1995). How many were at least "fairly well satisfied"? Almost 90 percent. Among those who recalled feeling *fair* or *very poor* when beginning therapy, 9 in 10 now were feeling *very good, good*, or at least *so-so*. Worldwide, most people report benefiting from

psychotherapy (Stein et al., 2020). We have clients' word for it—and who should know better?

We should not dismiss these testimonials. But consider some reasons for skepticism:

People often enter therapy in crisis. When, with the normal ebb and flow of events, the crisis passes, people may attribute their improvement to the therapy. Depressed people often get better no matter what they do.

Clients believe that treatment will be effective. The *placebo effect* is the healing power of positive expectations.

Clients generally speak kindly of their therapists. Even if the problems remain, clients "work hard to find something positive to say. The therapist had been very understanding, the client had gained a new perspective, [they] learned to communicate better, [their] mind was eased, anything at all so as not to have to say treatment was a failure" (Zilbergeld, 1983, p. 117).

Clients want to believe the therapy was worth the effort. If you invested time and money in something, wouldn't you be motivated to find something positive about it? Psychologists call this *effort justification*.

Consider the testimonials gathered in a massive experiment with over 500 Massachusetts boys, aged 5 to 13 years, many of whom seemed bound for delinquency. By the toss of a coin, half the boys were assigned to a 5-year treatment program. The treated boys were visited by counselors twice a month. They participated in community

programs, and they received academic tutoring, medical attention, and family assistance as needed. Some 30 years later, Joan McCord (1978, 1979) located 485 participants, sent them questionnaires, and checked public records from courts, psychiatric hospitals, and other sources. Was the treatment successful?

Client testimonials were glowing. Some men noted that, had it not been for their counselors, "I would probably be in jail," "My life would have gone the other way," or "I think I would have ended up in a life of crime." Court records offered apparent support: Even among the "difficult" boys in the treatment group, 66 percent had no official juvenile crime record.

But recall psychology's most powerful tool for sorting reality from wishful thinking: the *control group*. For every boy in the treatment group, there was a similar boy in a control group receiving no counseling. Of these untreated men, *70 percent* had no juvenile record. On several other measures, such as a record of having committed a second crime, alcohol use disorder, death rate, and job satisfaction, the untreated men exhibited slightly *fewer* problems. Unfortunately, the glowing testimonials of those treated were misleading.

Clinician Perceptions

If clinician perceptions were proof of therapy's effectiveness, we would have even more reason to celebrate. Case studies of successful treatment abound. The problem is that clients enter psychotherapy

focused on their unhappiness and leave it focused on their well-being. Therapists treasure compliments from those clients saying good-bye or later expressing their gratitude. But they hear little from clients who experience only temporary relief and seek out new therapists for their recurring problems. Thus, therapists are most aware of the failures of *other* therapists. With the same recurring anxieties, depression, or marital difficulty, the same person may be a "success" story in several therapists' files. Moreover, therapists, like the rest of us, are vulnerable to cognitive errors. **Confirmation bias** can lead them to unconsciously seek evidence that confirms their beliefs and to ignore contradictory evidence, and *illusory correlations* can lead them to perceive associations that don't really exist (Lilienfeld et al., 2015).

Outcome Research

How, then, can we objectively measure the effectiveness of psychotherapy? What *outcomes* can we expect—what types of people and problems are helped, and by what type of psychotherapy?

In search of answers, psychologists have turned to the well-traveled path of controlled research. In the 1800s, skeptical physicians began to realize that many patients were dying despite receiving then-mainstream treatments (such as bloodletting), and many others were getting better on their own. Sorting fact from superstition required observing patients and recording outcomes with and without a particular treatment. Typhoid fever patients, for example, often

improved after bloodletting, convincing most physicians that the treatment worked. But when a control group was given mere bed rest, 5 weeks later 70 percent had improved, showing that the bloodletting was worthless (as reported in Thomas, 1992).

A similar result—and spirited debate—followed the summary of 24 studies of psychotherapy outcomes (Eysenck, 1952). Two-thirds of people who received psychotherapy for disorders not involving hallucinations or delusions improved markedly. To this day, no one disputes that optimistic estimate. But there was a catch. Similar improvement occurred among people who were *untreated,* such as those who sought treatment but were placed on waiting lists. With or without psychotherapy, roughly two-thirds improved noticeably. Time was a great healer.

Feng Li/Getty Images

Trauma and resilience Those who suffer through trauma, such as these women in China mourning the devastating loss of lives and homes in the 2010 Yushu earthquake, may benefit from counseling. But many people recover on their own or with the help of supportive relationships with family and friends. "Life itself still remains a very effective therapist," noted psychodynamic therapist Karen Horney (*Our Inner Conflicts*, 1945).

Later research revealed shortcomings in the 24-study summary's analyses and methods. The sample was small—only 24 outcome studies in 1952, compared with thousands available today. The best of these are *randomized clinical trials*, in which researchers randomly assign people on a waiting list to therapy or to no therapy. Later, they evaluate everyone and compare outcomes, using tests and assessments done by others who don't know whether therapy was given.

A glimpse of psychotherapy's overall effectiveness can then be provided by means of a **meta-analysis**, a statistical procedure that combines the conclusions of a large number of different studies. Simply said, a meta-analysis summarizes lots of studies' results. Therapists welcomed the first meta-analysis of some 475 psychotherapy outcome studies. It showed that the average therapy client ends up better off than 80 percent of the untreated individuals on waiting lists (**FIGURE 55.1**). Psychologist Mary Lee Smith and her

colleagues summed it up: “Psychotherapy benefits people of all ages as reliably as schooling educates them, medicine cures them, or business turns a profit” (Smith et al., 1980, p. 183).

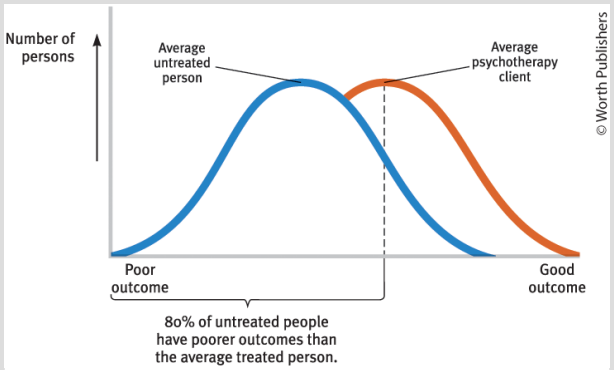


FIGURE 55.1 Treatment worked, as shown by the outcomes of treated versus untreated clients

Dozens of subsequent summaries have now examined psychotherapy’s effectiveness. Their verdict replicated earlier results: *Those not undergoing therapy often improve, but those undergoing therapy are more likely to improve—and to improve more quickly and with less risk of relapse* (Eckshtain et al., 2020; Weisz et al., 2017). (One qualification: Compared with studies that find no therapy benefit, those that do find a positive therapy effect are more likely to get published [Driessen et al., 2015].) After therapy, many people exhibit improved insight and emotional awareness, with a more patient, outgoing personality (Høglend & Hagtvet, 2019; Roberts et al., 2017). Some people with depression or anxiety also experience sudden symptom reductions

between their treatment sessions (Aderka et al., 2012). Those *sudden gains* bode well for long-term improvement (Shalom & Aderka, 2020).

Psychotherapy also can be cost-effective. Studies show that when people seek psychological treatment, their search for other medical treatment drops substantially—by 16 percent in one digest of 91 studies (Chiles et al., 1999). Substance abuse and other psychological disorders exert a staggering cost on society, including crime, accidents, and lost work. By one estimate, the opioid epidemic cost the United States more than $1 trillion between 2001 and 2017 (Altarum, 2018). Given such costs, psychotherapy is a good investment, much like investing time and money in healthy foods and exercise (de Oliveira et al., 2020; Johnson et al., 2019). Both reduce long-term costs. Boosting employees' psychological well-being can lower medical costs, improve work efficiency, and diminish absenteeism. It's no wonder that U.S. health insurers and the National Health Service in Britain have increasingly funded therapy (Hockenberry et al., 2019; NHS, 2020).

But note that the claim—that psychotherapy, *on average*, is somewhat effective—refers to no one therapy in particular. It is like reassuring lung-cancer patients that "on average," medical treatment of health problems is effective. But what distressed people—and those paying for their therapy—want to know is whether a *particular* treatment is effective for their specific problems.

Retrieval Practice

RP-1 How might the *placebo effect* bias clients' and clinicians' appraisals of the effectiveness of psychotherapies?

ANSWERS IN APPENDIX E

Which Psychotherapies Work Best?

LOQ 55-2

Are some psychotherapies more effective than others for specific disorders?

The early statistical summaries and surveys did not find that any one type of psychotherapy is generally superior (Smith & Glass, 1977; Smith et al., 1980). Later studies have similarly found that clients can benefit from psychotherapy regardless of their clinicians' experience, training, supervision, and licensing (Cuijpers, 2017; Kivlighan et al., 2015; Wampold et al., 2017). Were clients treated by a psychiatrist, psychologist, social worker, marriage counselor, or other mental health professional? Were they seen in a group or individual context? Did the therapist have extensive or relatively limited training and experience? It didn't matter.

So, was *Alice in Wonderland*'s dodo bird right: "Everyone has won and all must have prizes"? Not quite. One general finding emerges from

the studies: The more specific the problem, the greater the hope that psychotherapy might solve it (Singer, 1981; Westen & Morrison, 2001). Those who experience panic or specific phobias, who are unassertive, or who are frustrated by sexual performance problems can hope for improvement. Those with less-focused problems, such as depression and anxiety, usually benefit in the short term but often relapse later. There often is also an overlapping of disorders (*comorbidity*), which can make successful treatment more challenging.

Nevertheless, some forms of therapy do get prizes for effectively treating *particular* problems:

Cognitive and cognitive-behavioral therapies: primarily anxiety, panic disorder, posttraumatic stress disorder, insomnia, and depression (Qaseem et al., 2016; Scaini et al., 2016; Tolin, 2010).

Behavioral conditioning therapies: behavior problems such as bed-wetting, specific phobias, compulsions, marital difficulties, and sexual dysfunctions (Baker et al., 2008; Hunsley & DiGiulio, 2002; Shadish & Baldwin, 2005).

Psychodynamic therapy: depression and anxiety (Driessen et al., 2010; Leichsenring & Rabung, 2008; Shedler, 2010). Some analyses suggest that psychodynamic therapy and cognitive-behavioral therapy are equally effective in reducing depression (Driessen et al., 2017; Steinert et al., 2017).

Nondirective (person-centered) counseling: mild to moderate depression (Cuijpers et al., 2012).

> **"Different sores have different salves."** — English proverb

The tendency of many disordered states of mind to return to healthy states, combined with the placebo effect (the healing power of mere belief in a treatment), creates fertile soil for pseudotherapies. No prizes—and no scientific support—go to these alternative therapies (Arkowitz & Lilienfeld, 2006; Lilienfeld et al., 2015). We would all be wise to avoid therapies that propose to manipulate invisible "energy fields," therapies that reenact the supposed trauma of a client's birth, and therapies that use "facilitated communication," in which "responders" guide noncommunicative people's arms or hands to point to letters to compose messages.

Like some medical treatments, some psychological treatments are not only ineffective but also harmful. The American Psychiatric Association, the Canadian Psychological Association, and the British Psychological Society have warned against conversion therapies that purport to change people's gender identity or sexual orientation. APA president Barry Anton has described such therapies as an attempt to "repair … something that is not a mental illness and therefore does not require therapy" (2015). Indeed, conversion therapy entails "a significant risk of harm" (APA, 2018; Turban et al., 2020). Such evidence has led to conversion therapy bans in many cities, states, and countries, especially for minors. Other initiatives have been found ineffective or harmful (Walton & Wilson, 2018). These failed programs include the Scared Straight program designed to curb

teenage delinquency and the police-promoted D.A.R.E. anti-drug effort. Numerous weight-reduction programs, and several pedophile rehabilitation efforts have also proven unsuccessful.

The evaluation question—which therapies get prizes and which do not?—lies at the heart of what some call psychology's civil war. To what extent should science guide both clinical practice and insurers' willingness to pay for psychotherapy? On one side are research psychologists using scientific methods to extend the list of well-defined and validated therapies for various disorders. They decry clinicians who seem to "give more weight to their personal experience than to science" (Baker et al., 2008). On the other side are some therapists who view their practice as more art than science, arguing that people are too complex and psychotherapy is too intuitive to describe in a manual or test in an experiment.

Between these two factions stand the science-oriented clinicians calling for **evidence-based practice**, which has been endorsed by the American Psychological Association and others (APA, 2006; Holmes et al., 2018; Sakaluk et al., 2019; **FIGURE 55.2**). After rigorous evaluation, clinicians apply therapies suited to their own skills and their clients' unique situations. Some are using technology, too. By analyzing many pieces of clients' information, computer programs can help clinicians offer personalized therapeutic solutions (Ewbank et al., 2019; Webb et al., 2020). Increasingly, insurer and government support for mental health services require evidence-based practice.

FIGURE 55.2 Evidence-based practice Ideal clinical decision making can be visualized as a three-legged stool, upheld by research evidence, clinical expertise, and knowledge of the client.

Retrieval Practice

RP-2 Therapy is most likely to be helpful for those with problems that _____ (are/are not) well-defined.

RP-3 What is *evidence-based practice?*

ANSWERS IN APPENDIX E

How Do Psychotherapies Help People?

LOQ 55-3

What three elements are shared by all effective forms of psychotherapy?

Why have studies found little correlation between therapists' training and experience and clients' outcomes? One answer seems to be that all effective psychotherapies share three basic benefits (Cuijpers et al., 2019; Frank, 1982; Wampold, 2007):

- ***Hope for discouraged people*** People seeking therapy typically feel anxious, depressed, self-disapproving, and incapable of turning things around. What any psychotherapy offers is the expectation that, with commitment from the therapy seeker, things can and will get better. This belief, apart from any therapeutic technique, may improve morale, create feelings of self-efficacy, and diminish symptoms (Corrigan, 2014; Meyerhoff & Rohan, 2016).
- ***A new perspective*** Every therapy offers people a plausible explanation of their symptoms. Armed with a believable fresh perspective, they may approach life with a new attitude, open to making changes in their behaviors and their views of themselves.
- ***An empathic, trusting, caring relationship*** No matter what technique they use, effective therapists are empathic. They seek to understand the client's experience. They communicate care and concern, and they earn trust through respectful listening and guidance (Ovenstad et al., 2020). These qualities were clear in

recorded therapy sessions from 36 recognized master therapists (Goldfried et al., 1998). Some took a cognitive-behavioral approach. Others used psychodynamic principles. Although the master therapists used different approaches, they showed some striking *similarities*. They helped clients evaluate themselves, link one aspect of their life with another, and gain insight into their interactions with others. The emotional bond between therapist and client—the **therapeutic alliance**—helps explain why empathic, caring therapists are especially effective (Flückiger et al., 2020). Whether experienced in Canada or Cambodia, a strong therapeutic alliance fosters psychological health (Falkenström et al., 2019; Gold, 2019). It may even save lives. In one analysis of a dozen studies, a strong therapeutic alliance predicted less frequent suicidal thoughts, self-harming behaviors, and suicide attempts (Dunster-Page et al., 2017).

"The thing is, you have to really want to change."

These three common elements—hope, a fresh perspective, and an empathic, caring relationship—help us understand why

paraprofessionals (briefly trained caregivers, who sometimes have firsthand experience with a specific mental health challenge) can assist many troubled people so effectively (Bryan & Arkowitz, 2015; Christensen & Jacobson, 1994). They are also part of what the growing numbers of in-person and online *self-help and support groups* offer their members. And they are part of what traditional healers have offered (Jackson, 1992). Healers everywhere—special people to whom others disclose their suffering, whether psychiatrists or shamans—have listened to understand and to empathize, reassure, advise, console, interpret, or explain (Torrey, 1986). Such qualities may explain why people who feel supported by close relationships—who enjoy the fellowship and friendship of caring people—have been less likely to seek therapy (Frank, 1982; O'Connor & Brown, 1984).

Rainer Kwiotek/Friendship Bench

Friendship bench Some Zimbabwe health clinics have added outdoor "friendship benches," where paraprofessional community health workers offer therapy (Chibanda et al., 2016). Psychiatrist Dixon Chibanda created this free therapy for rural communities after a client, lacking bus fare to get to Chibanda's office, died by suicide. "We have to take

> [psychiatry] to the community," Chibanda said (Rosenberg, 2019).

***

To recap, people who seek help usually improve. So do many of those who do not, which is a tribute to our human resourcefulness and our capacity to care for one another. Nevertheless, though the therapist's orientation and experience appear not to matter much, people who receive some psychotherapy usually improve more than those who do not. People with clear-cut, specific problems tend to improve the most.

Ask Yourself

Based on what you've read, would you seek therapy if you were struggling with a mental health challenge? Why or why not? If you've experienced therapy, does what you've learned here influence your feelings about the experience?

Retrieval Practice

RP-4 Those who undergo psychotherapy are _____ (more/less) likely to show improvement than those who do not undergo psychotherapy.

ANSWERS IN APPENDIX E

Human Diversity and Psychotherapy

LOQ 55-4

What personal factors influence the therapist-client relationship?

All psychotherapies offer hope, and nearly all psychotherapists attempt to enhance their clients' sensitivity, openness, personal responsibility, and sense of purpose (Jensen & Bergin, 1988). But in matters of culture, values, and personal identity, psychotherapists differ from one another and may differ from their clients (Delaney et al., 2007; Kelly, 1990).

These differences can create a mismatch—for example, when a therapist from one culture interacts with a client from another. Therapists tend to prefer clients who are culturally similar to themselves (Desai et al., 2021). In North America, Europe, and Australia, most psychotherapists reflect their culture's *individualism*, which often gives priority to personal desires and identity. Clients with a *collectivist* perspective, as with many from Asian cultures, may be more mindful of social and family responsibilities, harmony, and group goals. These clients may have trouble relating to therapists who ask them to think only of their own well-being (Markus & Kitayama, 1991). In one experiment, Asian American clients matched with counselors who shared their cultural values (rather than mismatched with those who did not) perceived more counselor empathy and felt a stronger alliance with the counselor (Kim et al., 2005).

Client-psychotherapist mismatches may also stem from other personal differences. Highly religious people may prefer and benefit from religiously similar therapists who share their values and beliefs (Masters, 2010; Pearce et al., 2015). Likewise, therapists' attitudes toward LGBTQ people can affect the client-therapist relationship. Transgender people, for example, may understandably seek out therapists who affirm them (Bettergarcia & Israel, 2018).

AAMIR QURESHI/AFP/Getty Images

Meeting the needs of the community In 2021, the Pakistani government opened this Transgender Protection Center to provide legal aid, health services, and psychological counseling for the transgender community.

Cultural differences help explain some groups' reluctance to use mental health services (Eken et al., 2021). People living in "cultures of honor" (Social Psychology modules) prize being strong and tough. They may feel that seeking mental health care is an admission of weakness rather than an opportunity for growth (Brown et al., 2014). Refugees, despite having frequently endured trauma and discrimination, tend to avoid seeking mental health services due to

distrust, poverty, and language barriers (Byrow et al., 2020). And some cultural groups tend to be both reluctant to seek therapy and quick to leave it (Chen et al., 2009; Sue et al., 2009). Hesitancy to seek psychotherapy is often higher among African Americans than for other groups, due to social pressure against seeking help, mistrust of therapists, and microaggressions experienced during therapy (Taylor & Kuo, 2018).

The bottom line: By building their *cultural competence*—understanding and respecting different cultural groups' values, beliefs, and traditions—therapists can better serve their clients (Soto et al., 2018).

Seeking Psychotherapy

LOQ 55-5

When should people seek therapy, and what should they look for when selecting a therapist?

Life for everyone is marked by a mix of serenity and stress, blessing and bereavement, good moods and bad. So, when should we seek a mental health professional's help? The American Psychological Association offers these trouble signals:

- Feelings of hopelessness
- Deep and lasting depression
- Self-destructive behavior, such as substance abuse and self-injury

- Disruptive fears
- Sudden mood shifts
- Thoughts of suicide
- Compulsive rituals, such as lock checking
- Sexual difficulties
- Hearing voices or seeing things that others don't experience
- Struggling to understand others' thoughts and emotions

In looking for a psychotherapist, you may want to have a preliminary session with two or three. Meeting with more than one therapist gives you multiple opportunities to find someone with whom you feel comfortable. College or university health centers are generally good starting points; you may be able to access qualified therapists and some free services by browsing their web page or visiting in person. You may also get a referral from your primary care provider or visit a walk-in clinic. If you have insurance coverage, your provider may supply a list of participating therapists. Many people also use the internet to search for therapists, and many receive help online or via one of the more than 10,000 mental health apps (Kocsis, 2018; Levin et al., 2018; Nielssen et al., 2019). Therapist-guided treatment online or via apps can help reduce depression, social anxiety disorder, and panic disorder (Niles et al., 2021). Being able to meet remotely with a therapist has helped people who may struggle to attend in-person sessions (Guo et al., 2020; Markowitz et al., 2021). Such online therapy also offered a useful alternative solution when it was unsafe to attend in-person therapy sessions during the Covid-19 pandemic.

> **"Being physically present with a client does not appear essential to generating therapeutic outcomes."** — Psychologist Ashley Batastini and colleagues (2020)

During your in-person or remote session, you can describe your problem and learn each therapist's treatment approach. You can ask questions about the therapist's values, credentials (TABLE 55.1), and fees. And you can assess your own feelings about each therapist. The emotional bond between therapist and client is perhaps the most important factor in effective therapy.

TABLE 55.1 Therapists and Their Training

Type	Description
Clinical psychologists	Most are psychologists with a Ph.D. (includes research training) or Psy.D. (focuses on therapy) supplemented by a supervised internship and, often, postdoctoral training. About half work in agencies and institutions, half in private practice.
Psychiatrists	Psychiatrists are physicians who specialize in the treatment of psychological disorders. Not all psychiatrists have had extensive training in psychotherapy, but as M.D.s or D.O.s they can prescribe medications. Thus, they tend to see those with the most serious problems. Many have their own private practice.
Clinical or psychiatric social workers	A master of social work (M.S.W.) plus postgraduate supervision prepares some social workers to offer psychotherapy, mostly to people with everyday personal and family problems. About half of U.S. social workers have earned the National Association of Social Workers' designation of clinical social worker.

Counselors	Family and couples counselors specialize in problems arising from family relations. Clergy provide counseling to countless people. Counselors may work with people with substance use disorders and with spouse and child abusers and victims of abuse. Mental health and other counselors may be required to have a master's degree.

Macmillan Learning

Therapy for all Therapy was once available only for the wealthy and well-connected. Teletherapy, low-cost and no-cost community programs, and mental health apps have put help just a few clicks away.

The American Psychological Association recognizes the importance of a strong therapeutic alliance, and it welcomes diverse therapists who can relate well to diverse clients. It accredits programs that provide training in cultural sensitivity (for example, to differing values,

communication styles, and languages) and that recruit underrepresented cultural groups.

Ethical Principles in Psychotherapy

LOQ 55-6

What ethical principles guide psychotherapy and psychological research on mental illness?

Psychotherapists use different approaches to help reduce their clients' suffering. Likewise, researchers apply many methods to understand how to lessen people's disordered thoughts, feelings, and behaviors. But before psychotherapists or researchers begin their treatment or investigation, they must follow their country's ethical principles and code of conduct (APA, 2017).

According to the American Psychological Association, your therapist should follow these principles:

- Seek to benefit you and do you no harm.
- Establish a feeling of trust and a defined role as your therapist, as well as be of service to the therapeutic community.
- Be honest, truthful, and accurate.
- Be fair and promote justice for you and others, helping everyone to have access to the benefits of therapy.

- Respect the dignity and worth of you and others, recognizing the right to privacy, confidentiality, and self-determination.

Psychological researchers use the same ethical guidelines when studying how to lessen mental illness. They aim to benefit others, to be honest and truthful, and to never expose people to experiences that pose greater than a *minimal risk*—to more than what people may encounter in their daily lives.

Retrieval Practice

RP-5 There are many acceptable mental health treatment and study approaches, but all therapists and psychological researchers must follow _____ principles.

evidence-based practice

therapeutic alliance

Module Test

Test Yourself Answer the following questions on your own first, then "show" the answers here, or check your answers in Appendix E.

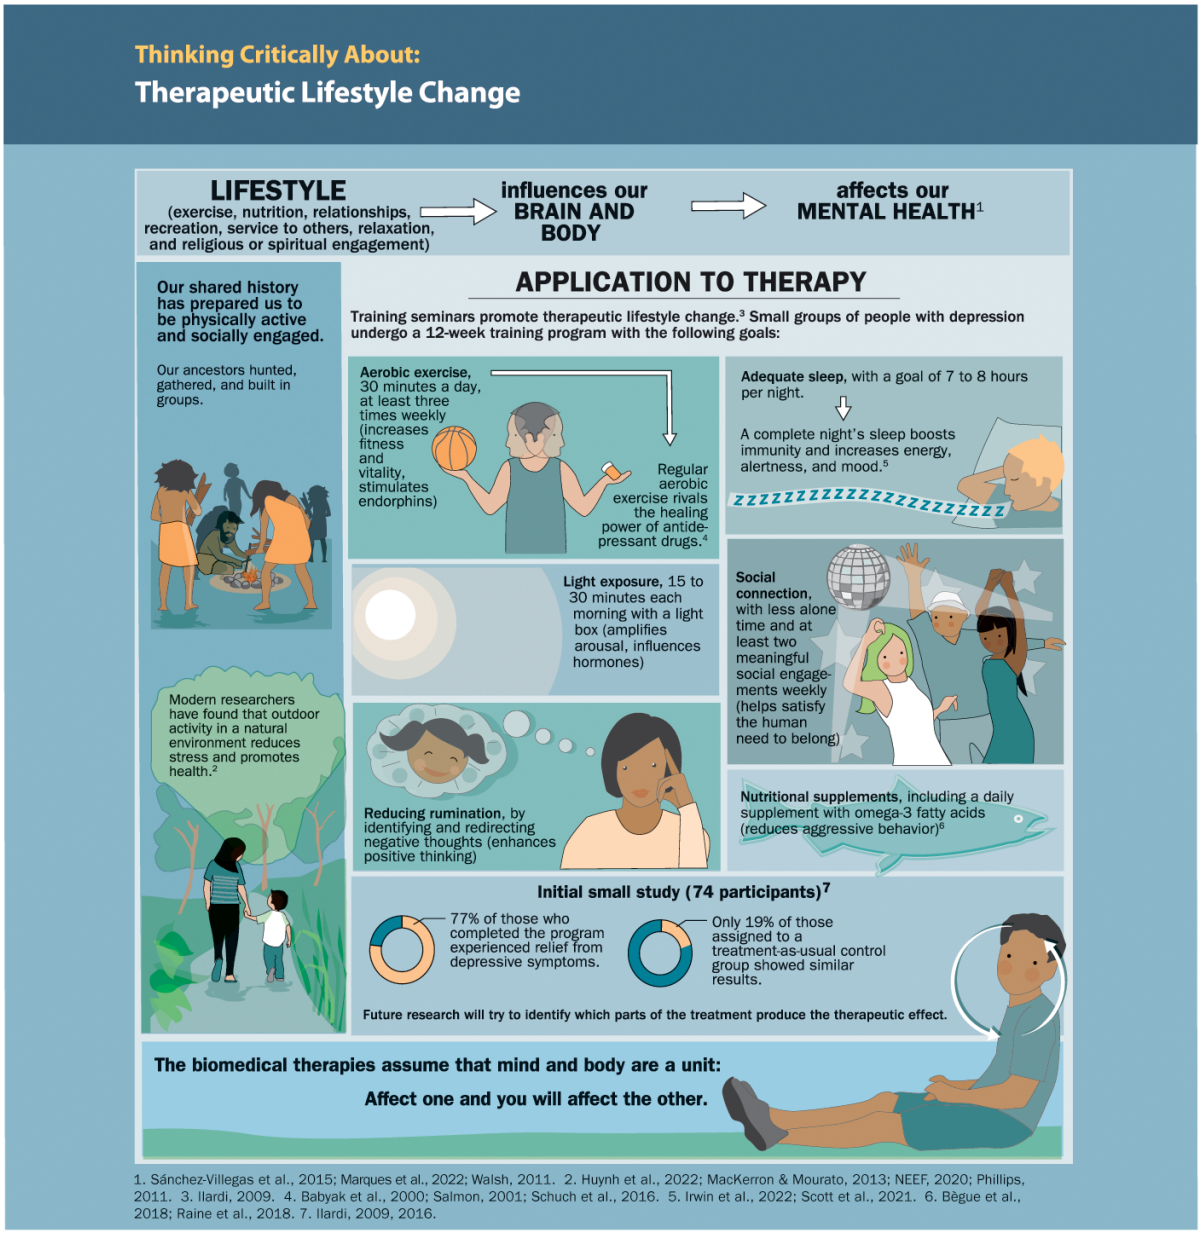
1. The most enthusiastic or optimistic view of the effectiveness of psychotherapy comes from
   a. outcome research.
   b. randomized clinical trials.
   c. reports of clinicians and clients.
   d. a government study of treatment for depression.

2. Studies show that _____ therapy is the most effective treatment for most psychological disorders.
   a. behavior
   b. humanistic
   c. psychodynamic
   d. no one type of

3. What are the three components of evidence-based practice?

4. Psychotherapies help people by providing _____, a new perspective, and an empathic, trusting, caring

relationship.



MODULE 56: The Biomedical Therapies and Preventing Psychological Disorders

Psychotherapy is one way to treat psychological disorders. The other is **biomedical therapy**. Biomedical treatments can change the brain's chemistry with drugs; affect its circuitry with electrical stimulation, magnetic impulses, or psychosurgery; or influence its responses with lifestyle changes.

Are you surprised to find *lifestyle changes* in this list? We find it convenient to talk of separate psychological and biological influences, but everything psychological is also biological. Thus, our lifestyle—exercise, sleep, nutrition, relationships, recreation, relaxation, religious or spiritual engagement, and our service to others—affects our mental health (Bennie et al., 2020; Walsh, 2011). (See Thinking Critically About: Therapeutic Lifestyle Change.)

LOQ 56-1

Why is therapeutic lifestyle change considered an effective biomedical therapy, and how does it work?

© Worth Publishers

Every thought and feeling depends on the functioning brain. Every creative idea, every moment of joy or anger, every experience of depression emerges from the electrochemical activity of the living brain. Anxiety disorders, obsessive-compulsive disorder, posttraumatic stress disorder, depressive disorders, bipolar disorders,

and schizophrenia are all biological events. Some psychologists even see psychotherapy as a biological treatment: Changing the way we think and act is brain-changing (Kandel, 2013). When psychotherapy relieves behaviors associated with obsessive-compulsive disorder, depression, or schizophrenia, PET scans reveal a less agitated brain (Habel et al., 2010; Kennedy et al., 2007; Porto et al., 2009). As we have seen over and over, *a human being is an integrated biopsychosocial system*.

RP-1 What are some examples of lifestyle changes people can make to enhance their mental health?

ANSWERS IN APPENDIX E

Drug Therapies

LOQ 56-2

What are the drug therapies? How do double-blind studies help researchers evaluate a drug's effectiveness?

By far the most widely used biomedical treatments today are the drug therapies. Most drugs for anxiety and depression are prescribed by primary care providers, followed by psychiatrists and, in some U.S. states, psychologists.

Since the 1950s, **psychopharmacology** discoveries have revolutionized the treatment of people with severe disorders, liberating hundreds of thousands from hospital confinement. Thanks to drug therapies and community mental health programs, today's resident population of psychiatric hospitals has dropped to a small fraction of what it once was. For some who are unable to care for themselves, however, release from hospitals has meant experiencing homelessness, not liberation.

Almost any new treatment, including a drug therapy, is greeted by an initial wave of enthusiasm as many people apparently improve. But that enthusiasm often diminishes on closer examination. To evaluate any new drug's effectiveness, researchers also need to know the following:

- How many people recover *without* treatment, and how quickly?
- How does the drug therapy's effectiveness compare to that of nondrug treatments, like psychotherapy?

Is recovery due to the drug or to the placebo effect? When clients or mental health workers expect positive results, they may see what they expect, not what really happens. Even mere exposure to advertising about a drug's supposed effectiveness can increase its effect (Kamenica et al., 2013).

Peter C. Vey/Cartoon Stock

"If this doesn't help you don't worry, it's a placebo."

To control for these influences, drug researchers often give about half of study participants the drug, and the other half a similar-appearing placebo. Because neither the staff nor the participants know who gets which, this is called a *double-blind procedure*. The good news: Worldwide, double-blind studies show that several types of drugs effectively treat psychological disorders in children, adolescents, and adults (Correll et al., 2022; Leichsenring et al., 2022).

Antipsychotic Drugs

An accidental discovery launched a treatment revolution for people with hallucinations or delusions—what psychologists call *psychoses*. The discovery: Certain drugs, originally developed to reduce presurgical agitation, calmed these patients' split from reality. First-generation **antipsychotic drugs**, such as chlorpromazine (sold as Thorazine), helped people with schizophrenia who were experiencing auditory hallucinations and paranoia (Leucht et al., 2018).

(Antipsychotic drugs are less effective in changing negative symptoms, such as apathy and withdrawal.)

The molecules of most conventional antipsychotic drugs are similar enough to molecules of the neurotransmitter dopamine to occupy its receptor sites and block its activity. This finding reinforces the idea that an overactive dopamine system contributes to schizophrenia. Second-generation antipsychotics also act on serotonin systems.

Antipsychotics have powerful side effects. Some produce sluggishness, tremors, and twitches similar to those of Parkinson's disease (Kaplan & Sadock, 1989). Long-term use of antipsychotics can produce *tardive dyskinesia*, with involuntary motor movements of the facial muscles (such as grimacing), tongue, and limbs. Second-generation antipsychotics, such as clozapine (Clozaril), quetiapine (Seroquel), and olanzapine (Zyprexa), are less likely than first-generation antipsychotics to cause these effects. These drugs may, however, increase the risk of obesity and diabetes (Buchanan et al., 2010; Tiihonen et al., 2009). To identify doses that reduce symptoms with fewer side effects, researchers have combed through data for more than 20 antipsychotic medications (Leucht et al., 2020).

Perhaps you can guess an occasional side effect of L-dopa, a drug that raises dopamine levels for Parkinson's patients: hallucinations.

Antipsychotics, combined with life-skills programs and support from family and close others, have given new hope to many people with schizophrenia (Goff et al., 2017; Guo et al., 2010). Computer programs are beginning to help clinicians identify which people with schizophrenia will benefit from specific antipsychotic medications (Lee et al., 2018; Yu et al., 2018). Hundreds of thousands have returned to work and to near-typical lives due to symptom relief from these medications (Leucht et al., 2003; Saks, 2007).

USC Gould School of Law

Effective treatment Elyn Saks, a University of Southern California law professor, has written about what it's like to live with schizophrenia. Thanks to her treatment, which combines an antipsychotic drug and psychotherapy, she says, "Now I'm mostly well. I'm mostly

> thinking clearly. I do have episodes, but it's not like I'm struggling all of the time to stay on the right side of the line" (Saks, 2007).

Antianxiety Drugs

Antianxiety drugs, such as Xanax, Klonopin, and Ativan, depress central nervous system activity. Some antianxiety drugs have been successfully combined with psychological therapy to enhance exposure therapy's extinction of learned fears and to help relieve the symptoms of anxiety-related disorders, including posttraumatic stress disorder and obsessive-compulsive disorder (Davis, 2005; Kushner et al., 2007). Antianxiety drugs depress central nervous system activity, so they should not be used in combination with alcohol.

Some critics fear that antianxiety drugs may reduce symptoms without resolving underlying problems, especially when used as an ongoing treatment. "Popping a Xanax" at the first sign of tension can create a learned response: The immediate relief reinforces a person's tendencies to take drugs when anxious and avoid learning how to cope with distressing situations. Antianxiety drugs can also be addictive. Regular users who stop taking these drugs may experience increased anxiety, insomnia, and other withdrawal symptoms.

Antidepressant Drugs

The **antidepressant drugs** were named for their ability to lift people up from a state of depression, and this was their main use until

recently. These drugs are now also increasingly used to treat anxiety disorders, obsessive-compulsive and related disorders, and posttraumatic stress disorder (Beaulieu et al., 2019; Merz et al., 2019; Slee et al., 2019). Many antidepressant drugs work by increasing the availability of neurotransmitters, such as norepinephrine or serotonin, which elevate arousal and mood and are scarce when a person experiences feelings of depression or anxiety.

The most prescribed drugs in this group, including Prozac and its cousins Zoloft and Paxil, work by prolonging the time serotonin molecules remain in the brain's synapses. They do this by blocking the normal reuptake process. Given their use in treating disorders other than depressive ones—from anxiety to strokes—these particular drugs are most often called *SSRIs (selective serotonin reuptake inhibitors)* rather than antidepressants (Kramer, 2011).

But be advised: Patients with depression who begin taking antidepressants do not wake up the next morning singing, "It's a beautiful day!" Antidepressants begin to influence neurotransmission within hours, but their full psychological effect may take 4 weeks. One possible reason for the delay is that increased serotonin promotes neural changes, including new synapses and *neurogenesis*—the birth of new brain cells—perhaps reversing stress-induced neuron loss (Launay et al., 2011; Nord et al., 2021).

Cognitive therapy, by helping people reverse their habitual negative thinking style, helps prevent depression, boosts drug-aided relief from

depression, and reduces posttreatment relapses (Amick et al., 2015; Cuijpers et al., 2021). Some clinicians, for example, attack youth depression and anxiety from both below and above (Strawn et al., 2022): They use antidepressant drugs to work, bottom-up, on the emotion-related limbic system. And they use cognitive-behavioral therapy to work, top-down, to change frontal lobe activity and thinking.

Researchers agree that many people with depression often improve after a month on antidepressant drugs. But after allowing for natural recovery and the placebo effect, how big is the effect? The effect is consistent but, critics argue, not very big (Cipriani et al., 2018; Kirsch, 2010). In double-blind clinical trials, placebos produced improvement comparable to about 75 percent of the active drug's effect. For those with severe depression, there is less of a placebo effect and the added drug benefit is somewhat greater (Fournier et al., 2010; Kirsch et al., 2008; Olfson & Marcus, 2009). Antidepressants can have negative side effects, such as increased appetite, nausea, fatigue, reduced sex drive, and withdrawal symptoms when discontinued (Horowitz & Wilcock, 2022). So some clinicians advise beginning with psychotherapy before introducing antidepressants (Strayhorn, 2019; Svaldi et al., 2019). "If [drugs] are to be used at all," notes Irving Kirsch (2016), "it should be as a last resort."

Antidepressant drugs are not the only way to boost our mental health. Aerobic exercise can also reduce anxiety and depression. Combining exercise with psychotherapy produces a particularly powerful

antidepressant effect (Lee et al., 2021). For adults worldwide, three or more weekly exercise hours predicts a lower risk of future depression and a greater sense of life purpose (Choi et al., 2019; Schuch et al., 2018; Yemiscigil & Vlaev, 2021). *The point to remember*: If you're concerned about your mental health, consult a mental health professional to determine the best treatment for you.

Paul Noth/Cartoon Stock

"Of course you feel great.
These things are loaded with antidepressants."

Psychedelic Drugs

For those who have a depressive or anxiety disorder, suicidal thoughts, posttraumatic stress disorder (PTSD), or a substance use disorder, researchers are assessing possible benefits of small doses of **psychedelic drugs** (Reiff et al., 2021). Proponents claim that, when psychedelics are administered under guided conditions and in combination with psychotherapy, *microdosing* works quickly and with few side effects.

After preparatory talk therapy sessions, the typical client might swallow a pill that administers a small drug dose in a safe, comfortable setting. Over the next several hours, the lying-down client, perhaps wearing eyeshades and listening to calm music, may experience striking visions, emotions, and memories. Talk therapy then helps the client process the experience, which they may repeat in additional sessions.

> **"One good way to understand a complex system is to disturb it and then see what happens."** — Michael Pollan, *How to Change Your Mind: What the New Science of Psychedelics Teaches Us About Consciousness, Dying, Addiction, Depression, and Transcendence*, 2018

The drugs in this group include ketamine (an anesthetic that is also sometimes used as a risky party drug), psilocybin (the active ingredient in "magic mushrooms"), and MDMA (also known as Ecstasy).

Damon Casarez/The New York Times/Redux Pictures

Psychedelics offer a new perspective Jose Martinez is a former Army gunner whose legs and right arm were blown off by a roadside bomb in Afghanistan. To cope with chronic pain and suicidal thoughts, Martinez has turned to the psychedelic drug psilocybin. “Psychedelics helped me realize that my problems are small compared to the world’s bigger problems,” he says (Jacobs, 2021).

Ketamine. Dozens of experiments show that ketamine can provide relief from depression and suicidal thinking within hours (Alnefeesi et al., 2022; Riggs & Gould, 2021). Those dependent on alcohol use have also become more abstinent after ketamine treatment (Dakwar et al.,

2019; Grabski et al., 2022). But ketamine is not a magic bullet. Relief often dissipates, which raises questions about the risks of repeated use (Schatzberg, 2019; Zimmermann et al., 2020). Given that ketamine acts as an opioid, one skeptic wonders if ketamine clinics are "nothing more than modern opium dens" (George, 2018). But others note that ketamine stimulates new synapses, which for some aids lasting change (Beyeler, 2019).

Psilocybin. Experiments have found psilocybin-assisted therapy benefits at least equal to those of antidepressant drugs, and with fewer side effects (Carhart-Harris et al., 2021; Davis et al., 2021; Gukasyan et al., 2022). Microdosing psilocybin has also produced relief from excessive drinking. In one experiment, nearly half of those receiving psilocybin were abstinent 8 months later, as were only a quarter of those who received a placebo (Bogenschutz et al., 2022). One apparent reason for the lessened depression and alcohol use: The drug-assisted treatment stimulates brain cell growth and increases neural network connections (Daws et al., 2022). But the mind matters, too. Psilocybin's benefits are enhanced when patients have positive expectations (Gill et al., 2022; Kaertner et al., 2021).

MDMA. When paired with psychotherapy, MDMA has offered relief to people who for years had struggled with severe PTSD. In one experiment, 90 people across clinical sites in Canada, the United States, and Israel received either MDMA in three 8-hour sessions, or a placebo (Mitchell et al., 2021). By the end of the 18-week study, 67 percent of those who microdosed MDMA, and 32 percent of those who received the placebo, no longer had clinical PTSD.

Stay tuned. More clinical trials (experiments) are underway, and as many as 50 companies are working to make psychedelics into a billion-dollar business (Smith, 2022). Soon we will know whether psychedelic-assisted therapy is a revolutionary therapeutic aid—for many, the trip of a lifetime—or another therapeutic fad that flourishes and fades.

Mood-Stabilizing Medications

In addition to antipsychotic, antianxiety, and antidepressant drugs, psychiatrists have *mood-stabilizing drugs* in their arsenal. One of them, Depakote, was originally used to treat epilepsy. It also controlled the manic episodes associated with bipolar disorders. Another, the simple salt *lithium*, effectively levels the emotional highs and lows of bipolar disorders.

In the 1940s, Australian physician John Cade discovered that lithium calmed guinea pigs. Wondering if it might do the same for humans, he first tried it himself (to confirm its safety) and then on 10 people with mania—all of whom improved dramatically (W. Brown, 2019). About 7 in 10 people with bipolar disorders benefit from a long-term daily dose of this cheap salt, which helps prevent or ease manic episodes and, to a lesser extent, lifts depression (Solomon et al., 1995). Kay Redfield Jamison (1995) described the effect:

> Lithium prevents my seductive but disastrous highs, diminishes my depressions, clears out the wool and webbing from my disordered thinking, slows me down, gentles me out, keeps me from ruining my career and

> relationships, keeps me out of a hospital, alive, and makes psychotherapy possible. (pp. 88–89)

Among people with bipolar disorders, taking lithium also correlates with a greatly lowered risk of suicide (Oquendo et al., 2011). Naturally occurring lithium in drinking water has also correlated with lower suicide rates (across 808 Japanese cities and towns) and lower crime rates (across 27 Texas counties) (Kugimiya et al., 2021; Schrauzer & Shrestha, 1990, 2010). Lithium works.

ANSWERS IN APPENDIX E

Brain Stimulation

LOQ 56-3

How are brain stimulation and psychosurgery used in treating specific disorders?

Electroconvulsive Therapy

Another biomedical treatment, **electroconvulsive therapy (ECT)**, manipulates the brain with mild electric shocks. When ECT was introduced in 1938, the wide-awake person was strapped to a table and jolted with electricity to the brain. This early ECT, which produced convulsions and brief unconsciousness, gained a barbaric image. Today's ECT is much kinder and gentler, and no longer "convulsive." The person receives a general anesthetic and a muscle relaxant (to prevent bodily convulsions). A psychiatrist then delivers a brief electrical pulse, sometimes only to the brain's right side, which triggers a 30- to 60-second brain seizure (McCall et al., 2017). Within 30 minutes, the person awakens and remembers nothing of the treatment or of the preceding hours. The mysteriously effective treatment is roughly similar to rebooting a computer.

Many studies confirm that ECT effectively treats severe depression in "treatment-resistant" people who have not responded to drug therapy (Fink, 2009; Giacobbe et al., 2018; Ross et al., 2018). After three such sessions each week for 2–4 weeks, 70 percent or more of those receiving today's ECT improve markedly, with less memory loss than with earlier versions of ECT and without discernible brain damage or increased dementia risk (Osler et al., 2018). ECT also reduces suicidal thoughts, making it "often life-saving" (Maixner et al., 2021; Rhee et al., 2021). A *Journal of the American Medical Association* editorial concluded that "the results of ECT in treating severe depression are

among the most positive treatment effects in all of medicine" (Glass, 2001).

> The medical use of electricity is an ancient practice. Physicians treated the Roman Emperor Claudius (10 B.C.E.–54 C.E.) for headaches by pressing electric eels to his temples. Today, about 17 people per 100,000—people whose depression has not responded to other treatments—have received ECT (Lesage et al., 2016).

How does ECT alleviate severe depression—and, in some newer studies, mania (Elias et al., 2021)? After more than 80 years, no one knows for sure. One recipient likened ECT to the smallpox vaccine, which was saving lives before we knew how it worked. Perhaps the brief electric current calms neural centers where overactivity produces depression. Some research indicates that ECT stimulates neurogenesis (new neurons) and new synaptic connections (An & Wang, 2022).

No matter how impressive the results, the idea of electrically shocking a person's brain still strikes many as barbaric, especially given our ignorance about why ECT works. Moreover, the mood boost may not last long. Many ECT-treated people eventually relapse back into depression, although relapses are somewhat fewer for those who also receive antidepressant drugs or do aerobic exercise (Rosenquist et al., 2016; Salehi et al., 2016). *The bottom line*: In the minds of many psychiatrists and clients, ECT is a lesser evil than severe depression's anguish and risk of suicide. After ECT, psychiatrist Rebecca Barchas

(2021) reported "regaining my joie de vivre, my high level of motivation, and my ability to make decisions."

Alternative Neurostimulation Therapies

Three other neural stimulation techniques—transcranial direct current stimulation, transcranial magnetic stimulation, and deep brain stimulation—also aim to treat the depressed brain (FIGURE 56.1).

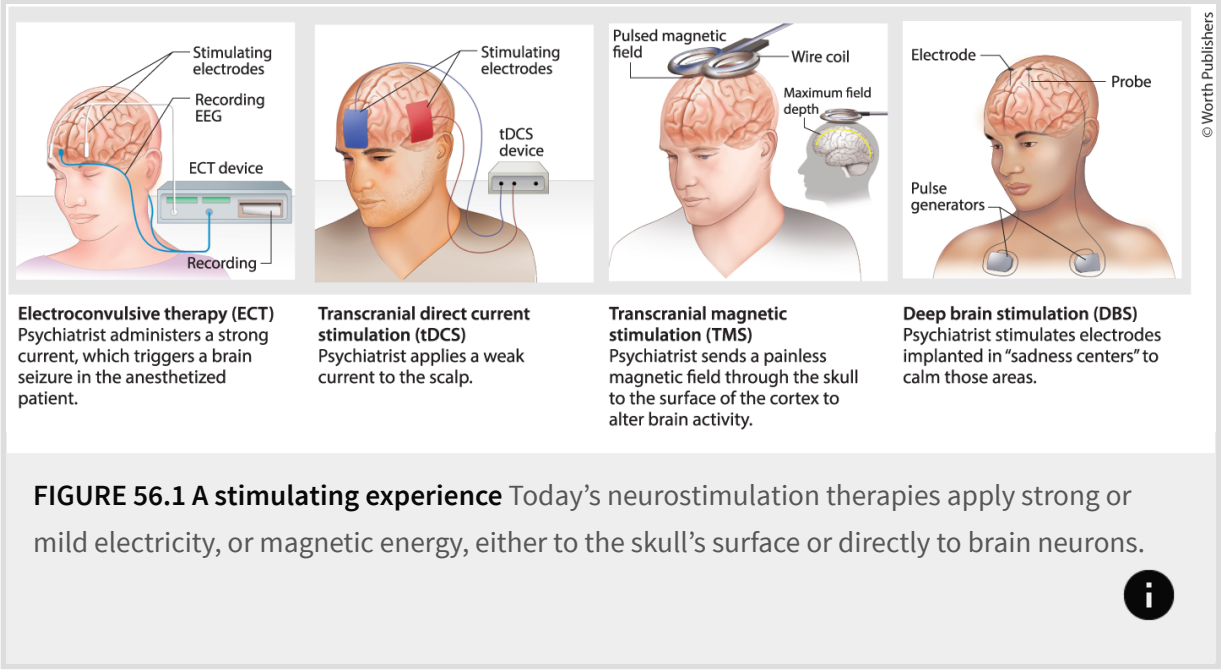

FIGURE 56.1 A stimulating experience Today's neurostimulation therapies apply strong or mild electricity, or magnetic energy, either to the skull's surface or directly to brain neurons.

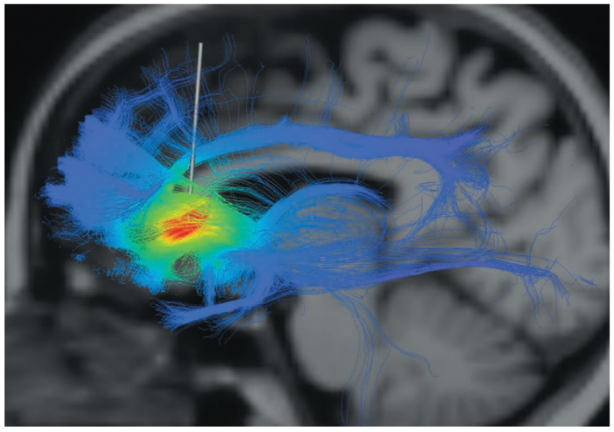
Transcranial Direct Current Stimulation

In contrast to ECT, which produces a brain seizure with about 800 milliamps of electricity, *transcranial direct current stimulation (tDCS)* administers a weak 1- to 2-milliamp current to the scalp. Skeptics argue that such a current is too weak to penetrate the brain

(Underwood, 2016). But research suggests that tDCS is a modestly effective treatment for depression and obsessive-compulsive disorder (Gao et al., 2022; Razza et al., 2020).

Transcranial Magnetic Stimulation

Depressed moods also sometimes improve when a painless procedure called **transcranial magnetic stimulation (TMS)** is performed on wide-awake patients in sessions over several weeks. Repeated pulses surging through a magnetic coil held close to the skull can stimulate or suppress activity in areas of the cortex. Like tDCS (and unlike ECT), the TMS procedure produces no memory loss or other serious side effects, aside from possible headaches.



Results are mixed. Some studies have found that, for 30 to 40 percent of people with depression, TMS works, although it is less effective than ECT (Carmi et al., 2019; Mutz et al., 2019). But researchers are exploring higher-dose and precisely targeted stimulation techniques that hold promise of greater relief (Cole et al., 2022; Ferrarelli & Phillips, 2021).

TMS also reduces some schizophrenia symptoms, such as social apathy and memory loss (Osoegawa et al., 2018; Xiu et al., 2020). How it works is unclear. Repeated stimulation may cause nerve cells to form new functioning circuits through *long-term potentiation*. Another possible explanation is a placebo effect: People benefit when, after being given a credible explanation, they *believe* TMS will work (Geers et al., 2019; Yesavage et al., 2018).

Deep Brain Stimulation

Other clients have benefited from an experimental treatment pinpointing a neural hub that bridges the thinking frontal lobes to the limbic system (Becker et al., 2016; Brunoni et al., 2017; Ryder & Holtzheimer, 2016). This area, which is overactive in the brain of a depressed or temporarily sad person, typically calms when treated by ECT or antidepressants. If not calmed, then to activate neurons that inhibit this negative activity, neuroscientist Helen Mayberg applied *deep brain stimulation (DBS)* technology, sometimes used to treat Parkinson's tremors. Since 2003, she and her colleagues have used DBS to treat more than 200 depressed patients via implanted electrodes in a brain area that functions as the neural "sadness center" (Lozano & Mayberg, 2015; Scangos et al., 2021). For some clients, DBS produces large and enduring reductions in depression (Crowell et al., 2019; Scangos et al., 2021). "The bottom line," notes Mayberg, "is that if you get better, you stay better" (Carey, 2019).

Left: Jared Siskin/Patrick McMullan/Getty Images; right: Helen Mayberg, M.D. Psychiatric Neuroimaging and Therapeutics, The Mayberg Lab at Emory University, Atlanta, GA/V. J. Wedeen and L.L.Wald/Athinoula A. Martinos Center For Biomedical Imaging and The Human Connectome Project, Boston, MA.

A depression switch? By comparing the brains of clients with and without depression, researcher Helen Mayberg identified a brain area (highlighted in red) that appears active in

people who are depressed or sad, and whose activity may be calmed by deep brain stimulation.

Psychosurgery

Because its effects are irreversible, **psychosurgery** is the most drastic and least-used biomedical intervention for changing behavior. In the 1930s, Portuguese physician Egas Moniz developed what would become the best-known psychosurgical operation: the **lobotomy**. Moniz found that cutting the nerves connecting the frontal lobes with the inner brain's emotion-controlling centers calmed uncontrollably emotional and violent patients. In what would later become, in others' hands, a crude but relatively simple procedure, a neurosurgeon would shock the patient into a coma, hammer an icepick-like instrument through the top of each eye socket into the brain, and then wiggle it to sever connections running up to the frontal lobes. Between 1936 and 1954, tens of thousands of people with mental illness were "lobotomized," including 35,000 in the United States alone (Valenstein, 1986).

Although the intention was simply to disconnect emotion from thought, the effect was often more drastic. A lobotomy usually decreased misery or tension, but also produced a permanently lethargic, immature, uncreative person. During the 1950s, when calming drugs became available, psychosurgery became scorned.

New York Times Co./Getty Images

Failed lobotomy This 1940 photo shows Rosemary Kennedy (center) at age 22 with brother (and future U.S. president) John and their sister Jean. When doctors suggested that a lobotomy would control Rosemary's reportedly violent mood swings, her father approved the procedure. The lobotomy, performed after this photo was taken, left her confined to a hospital with an infantile mentality for the next 63 years, until her death in 2005.

Today, lobotomies are history. More precise, microscale psychosurgery is sometimes used in extreme cases. For example, if a

person experiences uncontrollable seizures, surgeons can deactivate the specific nerve clusters that cause or transmit the convulsions. MRI-guided precision surgery is also occasionally done to cut the circuits involved in severe major depressive disorder and obsessive-compulsive disorder (Carey, 2009, 2011; M. Kim et al., 2018; Sachdev & Sachdev, 1997). Because these procedures are irreversible, neurosurgeons perform them only as a last resort.

***

TABLE 56.1 summarizes some aspects of the biomedical therapies we've discussed.

TABLE 56.1 Comparing Biomedical Therapies

Therapy	Targeted Problem	Therapy Aim	Therapy Technique
Therapeutic lifestyle change	Anxiety and depressive disorders	Restore healthy biological state.	Alter lifestyle through adequate exercise, sleep, nutrition, and other changes.
Drug therapies	Neurotransmitter malfunction	Control symptoms of psychological disorders.	Alter brain chemistry through drugs.
Brain stimulation	Depressive disorders and mania (ECT is used for severe, treatment-resistant depressive disorders, mania, and catatonia)	Alleviate depression and mania, especially when it is unresponsive to drugs or other forms of therapy.	Stimulate brain through electroconvulsive shock, mild electrical stimulation, magnetic pulses, or deep brain stimulation.

Psychosurgery	Brain malfunction	Relieve severe disorders.	Remove or destroy brain tissue.

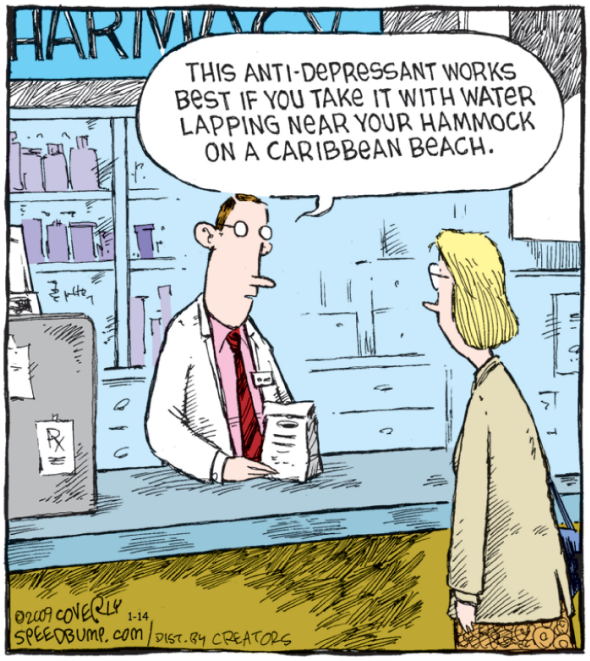
ANSWERS IN APPENDIX E

Preventing Psychological Disorders and Building Resilience



LOQ 56-4

What may help prevent psychological disorders, and why is it important to develop resilience?

Psychotherapies and biomedical therapies locate the cause of psychological disorders within the person. We infer that people who act cruelly must be cruel and that people who act "crazy" must be "sick." We attach labels to such people, thereby distinguishing them from "normal" folks. It follows, then, that we try to treat people with mental disorders by giving them insight into their problems, by changing their thinking, by helping them gain control with drugs.

There is an alternative viewpoint: We could interpret many psychological disorders as understandable responses to a disturbing and stressful world. According to this view, it is not just the person who needs treatment. Rather, as the soaring mental health problems during the Covid-19 pandemic illustrated, it's also the person's social context. It is better to prevent problems by reforming an unhealthy situation and developing people's coping competencies than to wait for and treat the problems that develop.

Life's stresses and challenges endure, and thus so do psychological disorders. Medical interventions such as antibiotics and vaccinations have greatly lengthened our life expectancy. Yet our growing understanding of suicide risks has not diminished suicide. Our understanding the neuroscience of addiction has been followed by *increased* overdose deaths. And more widely available psychotherapy has not reduced U.S. rates of depression and anxiety (Insel, 2022). So, what might we do to alleviate the root causes of such problems?

Preventive Mental Health

A story about the rescue of a drowning person from a rushing river illustrates this viewpoint: Having successfully administered first aid to the victim, the rescuer spots another struggling person and pulls that person out, too. After a half-dozen repetitions, the rescuer suddenly turns and starts running away while the river sweeps yet another floundering person into view. “Aren’t you going to rescue that person?” asks a bystander. “No way,” the rescuer replies. “I’m going upstream to find out what’s pushing all these people in.”

Preventive mental health is upstream work. It seeks to prevent psychological casualties by identifying and alleviating the conditions that cause them. As clinical psychologist George Albee (1986, 2006) pointed out, there is abundant evidence that poverty, safety concerns,

lack of meaningful work, constant criticism, unemployment, and discrimination undermine people's sense of competence, personal control, and self-esteem. Such stresses increase their risk of depression, substance use disorder, and suicide. To prevent psychological casualties we should, Albee contended, support programs that work to improve these distressing situations.

> **"It is better to prevent than to cure."** — Peruvian folk wisdom

Preventing psychological problems means empowering those who have learned an attitude of helplessness, and changing environments that breed loneliness, suicidal thinking, and excessive alcohol and drug use. It means teaching children how to manage their emotions, get along with others, and keep up with academic demands (Godwin, 2020). It means harnessing positive psychology interventions to enhance human flourishing. One intervention taught adolescents that personality isn't fixed—people can change—and reduced their chances of future depression by 40 percent (Miu & Yeager, 2015). This result is no fluke: Preventive therapies have consistently reduced the risk for depression (Breedvelt et al., 2018).

In short, "everything aimed at improving the human condition, at making life more fulfilling and meaningful, may be considered part of primary prevention of mental or emotional disturbance" (Kessler & Albee, 1975, p. 557). Prevention can sometimes provide a double payoff. People with a strong sense of life's meaning are more engaging

socially (Stillman et al., 2011). By strengthening people's sense of meaning in life, we may also lessen their loneliness as they become more engaging companions.

Among the upstream prevention workers are *community psychologists*. Mindful of how people interact with their environment, they focus on creating environments that support psychological health. Through their research and social action, community psychologists aim to empower people and to enhance their competence, health, and well-being.

> **"Mental disorders arise from physical ones, and likewise physical disorders arise from mental ones."** — *The Mahabharata*, 200 B.C.E.

Building Resilience

Preventive mental health includes efforts to build individuals' **resilience**.

Faced with extreme suffering or trauma, some people experience lasting harm, some experience stable resilience, and some experience growth (Myers, 2019). In the aftermath of the September 11, 2001, terror attacks, many New Yorkers exhibited resilience. This resilience was especially true for those who enjoyed supportive close relationships and who had not recently experienced other stressful events (Bonanno et al., 2007). More than 9 in 10 New Yorkers, although

stunned and grief-stricken by 9/11, did *not* have a dysfunctional stress reaction. Among those who did, the stress symptoms were mostly gone by the following January (Person et al., 2006). The initial isolation during the Covid-19 pandemic increased the rate of depressive disorders. But many people quickly adapted and their mental health returned to prepandemic levels (Robinson et al., 2022).

(a) (b)

Left: © Stephen Voss 2020/Redux Pictures; right: Chip Somodevilla/Getty Images

Disability and resilience (a) "I get to appreciate the gift of sight—any sight at all," said U.S. Congressman and Retired Navy SEAL Dan Crenshaw, who lost his eye to an improvised explosive device in the war in Afghanistan.

(b) "Sometimes it takes dealing with a disability—the trauma, the relearning, the months of rehabilitation therapy—to uncover our true abilities and how we can put them to work for us in ways we may have never imagined," said U.S. Senator and Retired Lieutenant Colonel Tammy Duckworth, who lost both legs as an Army helicopter pilot in the Iraq War.

Struggling with challenging crises can lead to **posttraumatic growth**. Many people who have lost a loved one to suicide have reported a greater appreciation for life, more meaningful relationships, and a

richer spiritual life (Levi-Belz et al., 2021). Out of even our worst experiences, some good can come, especially when we can imagine new possibilities (Mangelsdorf et al., 2019; Roepke, 2015). As with positive experiences, suffering can beget sensitivity and strength.

AJ Shorter Photography

Power and healing to the people APA President Thema Bryant aims to reduce negative outcomes among members of marginalized communities. “APA and the science of psychology,” she says, “are ideally situated to address the triple threat of trauma, loss and inequities that currently plagues our society” (APA, 2021).

Let the globe, if nothing else, say this is true:
That even as we grieved, we grew

That even as we hurt, we hoped
That even as we tired, we tried
— Poet Amanda Gorman, "The Hill We Climb" (U.S. Presidential inaugural poem, 2021)

Retrieval Practice

RP-5 What is the difference between preventive mental health and the psychological or biomedical therapies?

ANSWERS IN APPENDIX E

If you just finished reading this book, your introduction to psychological science is completed. Our tour of psychological science has taught us much—and you, too?—about our moods and memories, about the reach of our unconscious, about how we flourish and struggle, about how we perceive our physical and social worlds, and about how our biology and culture shape us. As your guides on this tour, we hope that you have shared our fascination, grown in your understanding and compassion, and sharpened your critical thinking. And we hope you enjoyed the ride.

With every good wish in your life journey ahead,

David G. Myers

REVIEW

Module 56: The Biomedical Therapies and Preventing Psychological Disorders

Learning Objectives

Test Yourself Answer these repeated Learning Objective Questions on your own (before "showing" the answers here, or checking the answers in Appendix D) to improve your retention of the concepts (McDaniel et al., 2009, 2015).

LOQ 56-1: Why is therapeutic lifestyle change considered an effective biomedical therapy, and how does it work?

LOQ 56-2: What are the drug therapies? How do double-blind studies help researchers evaluate a drug's effectiveness?

LOQ 56-3: How are brain stimulation and psychosurgery used in treating specific disorders?

LOQ 56-4: What may help prevent psychological disorders, and why is it important to develop resilience?

Terms and Concepts to Remember

Test Yourself Write down the definition in your own words, then check your answer.

biomedical therapy
psychopharmacology
antipsychotic drugs
antianxiety drugs
antidepressant drugs
psychedelic drugs
electroconvulsive therapy (ECT)
transcranial magnetic stimulation (TMS)
psychosurgery
lobotomy
resilience
posttraumatic growth

Module Test

Test Yourself Answer the following questions on your own first, then "show" the answers here, or check your answers in Appendix E.

1. Some antipsychotic drugs, used to calm people with schizophrenia, can have unpleasant side effects, most notably
   a. hyperactivity.
   b. momentary memory loss.
   c. sluggishness, tremors, and twitches.
   d. paranoia.

2. Drugs such as Xanax and Ativan, which depress central nervous system activity, can become addictive when used as ongoing treatment. These drugs are referred to as _____ drugs.

3. A simple salt that often brings relief to people with bipolar disorders is _____.

4. When drug therapies have not been effective, electroconvulsive therapy (ECT) may be used as a treatment for people with
   a. severe obsessive-compulsive disorder.
   b. severe depression.

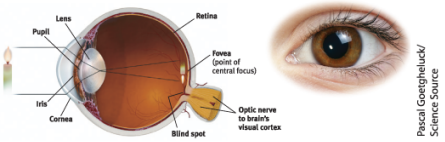
c. schizophrenia.
d. anxiety disorders.

5. An approach that seeks to identify and alleviate conditions that put people at higher risk for developing psychological disorders is called
   a. deep brain stimulation.
   b. the mood-stabilizing perspective.
   c. spontaneous recovery.
   d. preventive mental health.

Appendix A

The Story of Psychology: A Timeline

Charles L. Brewer, *Furman University*, and Salena Brody, *University of Texas, Dallas*



B.C.E.

387— Plato, who believed in innate ideas, suggests that the brain is the seat of mental processes.

335— Aristotle, who denied the existence of innate ideas, suggests that the heart is the seat of mental processes.

C.E.

1604— Johannes Kepler describes the inverted image on the retina.

Pascal Goetgheluck/ Science Source

Inverted image on the retina

1605— Francis Bacon publishes *The Proficiency and Advancement of Learning*.

1637— René Descartes, the French philosopher and mathematician who proposed mind–body interaction and the doctrine of innate ideas, publishes *A Discourse on Method*.

1690— John Locke, the British philosopher who rejected Descartes' notion of innate ideas and insisted that the mind at birth is a "blank slate" *(tabula rasa)*, publishes *An Essay Concerning Human Understanding*, which stresses empiricism over speculation.

1774— Franz Mesmer, an Austrian physician, performs his first supposed cure using "animal magnetism" (later called mesmerism and hypnosis). In **1777,** he was expelled from the practice of medicine in Vienna.

1793— Philippe Pinel releases the first psychiatric patients from their chains at the Bicêtre Asylum in France and advocates for more humane treatment of psychiatric patients.

1802— Thomas Young publishes *A Theory of Color Vision* in England. (His theory was later called the trichromatic theory.)

1808— Franz Joseph Gall, a German physician, describes phrenology, the false belief that the shape of a person's skull reveals mental faculties and character traits.

1813— The first private psychiatric hospital in the United States opens in Philadelphia.

1834— Ernst Heinrich Weber publishes *The Sense of Touch*, in which he discusses the "just noticeable difference (jnd)" and what we now call Weber's law.

1840— 

Dorothea Dix begins advocating for humane treatment of people in mental health institutions, persuading politicians to construct psychiatric hospitals.

Dorothea Dix (1802–1887)

All Portraits: Macmillan Learning

1844— In Philadelphia, 13 superintendents form the *Association of Medical Superintendents of American Institutions for the Insane* (now known as the American Psychiatric Association).

1848— Phineas Gage suffers massive brain damage when a large iron rod accidentally pierces his brain, leaving his intellect and memory intact but altering his personality.

Warren Anatomical Museum in the Francis A. Countway Library of Medicine. Gift of Jack and Beverly Wilgus.

Phineas Gage

1850— Hermann von Helmholtz measures the speed of the nerve impulse.

1859— Charles Darwin publishes *On the Origin of Species by Means of Natural Selection*, synthesizing much previous work on the theory of evolution, including that of Herbert Spencer, who coined the phrase "survival of the fittest."

1861— Paul Broca, a French physician, discovers an area in the left frontal lobe of the brain (now called Broca's area) that is critical for the production of spoken language.

1869— Francis Galton, Charles Darwin's cousin, publishes *Hereditary Genius*, in which he claims that intelligence is inherited. In **1876,** he coins the expression "nature and nurture" to correspond with "heredity and environment." Later, Galton proposes harmful ideas about how to improve the genetic quality of human populations (called *eugenics*) that would inform prejudiced and discriminatory policies.

1874— Carl Wernicke, a German neurologist and psychiatrist, shows that damage to a specific area in the left temporal lobe (now called Wernicke's area) disrupts ability to comprehend or produce spoken or written language.

1878— G. Stanley Hall receives from Harvard University's Department of Philosophy the first U.S. Ph.D. degree based on psychological research.

1879 

Wilhelm Wundt establishes at the University of Leipzig, Germany, the first psychology laboratory, which becomes a mecca for psychology students from all over the world.

Wilhelm Wundt (1832–1920)

1883 G. Stanley Hall, student of Wilhelm Wundt, establishes the first formal U.S. psychology laboratory at Johns Hopkins University.

1885 Hermann Ebbinghaus publishes *On Memory,* summarizing his extensive research on learning and memory, including the "forgetting curve."

1886 Joseph Jastrow receives from Johns Hopkins University the first Ph.D. degree awarded by a U.S. Department of Psychology.

1889 

Henri-Étienne Beaunis and Alfred Binet establish France's first psychology laboratory at the Sorbonne.

Alfred Binet (1857–1911)

The first International Congress of Psychology meets in Paris.

1890 

William James, Harvard University philosopher and psychologist, publishes *The Principles of Psychology,* describing psychology as "the science of mental life."

William James (1842–1910)

1891 James Mark Baldwin establishes the first psychology laboratory in the British Commonwealth at the University of Toronto.

1892 G. Stanley Hall spearheads the founding of the American Psychological Association (APA) and becomes its first president.

1893 

Mary Whiton Calkins and Christine Ladd-Franklin are the first women elected to membership in the APA.

Mary Whiton Calkins (1863–1930)

Christine Ladd-Franklin (1847–1930)

1894 Margaret Floy Washburn is the first woman to receive a Ph.D. degree in psychology (Cornell University).

Harvard University denies Mary Whiton Calkins admission to doctoral candidacy because of her gender. She goes on to publish more than 100 scientific articles related to memory and the self.

1896 John Dewey publishes "The Reflex Arc Concept in Psychology," helping to formalize the school of psychology called functionalism.

1898 In *Animal Intelligence,* Edward L. Thorndike describes his learning experiments with cats in "puzzle boxes." In **1905,** he proposes the "law of effect."

Doctoral student Alice Lee uses published data from the *Journal of Anatomy* to debunk the popular phrenology and eugenics arguments that skull size predicts intelligence.

1900 Sigmund Freud publishes *The Interpretation of Dreams,* his major theoretical work on psychoanalysis.

1901 Ten founders establish the British Psychological Society.

1904 Ivan Pavlov is awarded the Nobel Prize for Physiology or Medicine for his studies on the physiology of digestion.

1905 Mary Whiton Calkins becomes the first woman president of the APA.

Ivan Pavlov begins publishing studies of conditioning in animals.

Ivan Pavlov (1849–1936)

Alfred Binet and Théodore Simon produce the first intelligence test for assessing the abilities and academic progress of Parisian schoolchildren.

1909 

Sigmund Freud makes his only trip to America to deliver a series of lectures at Clark University.

Sigmund Freud (1856–1939)

1913 

John B. Watson outlines the tenets of behaviorism in a *Psychological Review* article, "Psychology as the Behaviorist Views It."

John Watson (1878–1958)

1914 Lillian Gilbreth publishes *Principles of Management,* a foundational text for the field of industrial-organizational psychology.

During World War I, Robert Yerkes and his staff develop a group intelligence test for evaluating U.S. military personnel, which increases the U.S. public's acceptance of psychological testing.

All Portraits: Macmillan Learning

1920 — 

Leta Stetter Hollingworth publishes *The Psychology of Subnormal Children,* an early classic. In **1921,** she is cited in *American Men of Science* for her research on the psychology of women.

Leta Stetter Hollingworth
(1886–1939)

Francis Cecil Sumner becomes the first Black person in the U.S. to receive a Ph.D. degree in psychology (Clark University). He later co-founds the psychology department at Howard University.

Francis Cecil Sumner
(1895–1954)

John B. Watson and Rosalie Rayner report conditioning a fear reaction in a child called "Little Albert."

1921 — Hermann Rorschach, a Swiss psychiatrist, introduces the Rorschach inkblot test.

1923 — Developmental psychologist Jean Piaget publishes *The Language and Thought of the Child.*

1924 — Mary Cover Jones reports reconditioning a fear reaction in a child (Peter), a forerunner of systematic desensitization developed by Joseph Wolpe.

1927 — In *Introduction to the Technique of Child Analysis,* Anna Freud discusses psychoanalysis in the treatment of children.

1929 — Wolfgang Köhler publishes *Gestalt Psychology,* which criticizes behaviorism and outlines essential elements of the gestalt theory.

1931 — 

Margaret Floy Washburn becomes the first female psychologist (and the second female scientist in any discipline) elected to the U.S. National Academy of Sciences.

Margaret Floy Washburn
(1871–1939)

1932 — In *The Wisdom of the Body,* Walter B. Cannon coins the term "homeostasis," discusses the fight-or-flight response, and identifies hormonal changes associated with stress.

1933 — 

Inez Beverly Prosser becomes the first Black woman to receive a Ph.D. degree in psychology from a U.S. institution (University of Cincinnati).

Inez Beverly Prosser
(1895–1934)

1934 — 

Ruth Winifred Howard becomes the second Black woman in the U.S. to receive a Ph.D. degree in psychology (University of Minnesota) and spends her career doing clinical work with children and young people.

Ruth Winifred Howard
(1900–1997)

1935 — Christiana Morgan and Henry Murray introduce the Thematic Apperception Test to elicit fantasies from people undergoing psychoanalysis.

1936 — Egas Moniz, a Portuguese physician, publishes work on the first frontal lobotomies performed on humans.

1938 — B. F. Skinner publishes *The Behavior of Organisms,* which describes operant conditioning of animals.

In *Primary Mental Abilities,* Louis L. Thurstone proposes seven such abilities.

Ugo Cerletti and Lucio Bini introduce electroshock treatment with a human patient.

1939 — David Wechsler publishes the Wechsler–Bellevue intelligence test, forerunner of the Wechsler Intelligence Scale for Children (WISC) and the Wechsler Adult Intelligence Scale (WAIS).

Mamie Phipps Clark receives a master's degree from Howard University. She later earns her doctorate and, with Kenneth B. Clark, provides joint research cited in the U.S. Supreme Court's 1954 decision to end racial segregation in public schools.

Mamie Phipps Clark
(1917–1983)

Edward Alexander Bott helps found the Canadian Psychological Association. He becomes its first president in 1940.

World War II provides many opportunities for psychologists to enhance the popularity and influence of psychology, especially in applied areas.

1941 — Raymond Cattell and John Horn distinguish fluid and crystallized intelligence. Decades later, John Carroll synthesizes these ideas as a bridge between a general intelligence factor (*g*) and specific abilities, to create the Cattell-Horn-Carroll (CHC) theory of intelligence.

1943 — Psychologist Starke Hathaway and physician J. Charnley McKinley publish the Minnesota Multiphasic Personality Inventory (MMPI).

1945 — 

Karen Horney, who criticized Freud's theory of female sexual development, publishes *Our Inner Conflicts.*

Karen Horney
(1885–1952)

All Portraits: Macmillan Learning

1946 U.S. Congress creates the National Institute of Mental Health, making mental health a national priority.

Benjamin Spock's first edition of *The Commonsense Book of Baby and Child Care* appears; the book will influence child raising in North America for several decades.

1948 Alfred Kinsey and his colleagues publish *Sexual Behavior in the Human Male,* and they publish *Sexual Behavior in the Human Female* in **1953.**

B. F. Skinner's novel, *Walden Two,* describes a utopian community based on positive reinforcement, which becomes a clarion call for applying psychological principles in everyday living, especially communal living.

B. F. Skinner
(1904–1990)

Ernest R. Hilgard publishes *Theories of Learning,* which was required reading for several generations of psychology students in North America.

1949 Raymond B. Cattell publishes the Sixteen Personality Factor Questionnaire (16PF).

The scientist-practitioner model of training is approved at the Boulder Conference on Graduate Education in Clinical Psychology.

In *The Organization of Behavior: A Neuropsychological Theory,* Canadian psychologist Donald O. Hebb outlines a new and influential conceptualization of how the nervous system functions.

1950 Solomon Asch publishes studies of effects of conformity on judgments of line length.

In *Childhood and Society,* Erik Erikson outlines his stages of psychosocial development.

1951 Carl Rogers publishes *Client-Centered Therapy.*

1952 The American Psychiatric Association publishes the *Diagnostic and Statistical Manual of Mental Disorders,* an influential book that will be updated periodically.

1953 Eugene Aserinsky and Nathaniel Kleitman describe rapid eye movements (REM) that occur during sleep.

Janet Taylor's Manifest Anxiety Scale appears in the *Journal of Abnormal Psychology.*

1954 In *Motivation and Personality,* Abraham Maslow proposes a hierarchy of motives ranging from physiological needs to self-actualization. (Maslow later updates the hierarchy to include self-transcendence needs.)

James Olds and Peter Milner, McGill University neuropsychologists, describe the rewarding effects of electrical stimulation of the hypothalamus in rats.

Gordon Allport publishes *The Nature of Prejudice.*

1956 In his *Psychological Review* article titled "The Magical Number Seven, Plus or Minus Two: Some Limits on Our Capacity for Processing Information," George Miller coins the term "chunk" for memory researchers.

1957 Robert Sears, Eleanor Maccoby, and Harry Levin publish *Patterns of Child Rearing.*

Charles Ferster and B. F. Skinner publish *Schedules of Reinforcement.*

1958 Harry Harlow publishes "The Nature of Love," outlining his work on attachment in monkeys.

1959 Noam Chomsky's critical review of B. F. Skinner's *Verbal Behavior* appears in the journal *Language.*

Keturah Whitehurst becomes the first Black person in the U.S. to be licensed as a psychologist. She later co-founds a human development and learning laboratory that provides educational opportunities to children in need.

Keturah Whitehurst
(1912–2000)

Eleanor Gibson and Richard Walk report their research on infants' depth perception in "The Visual Cliff."

Lloyd Peterson and Margaret Peterson, in the *Journal of Experimental Psychology* article, "Short-Term Retention of Individual Verbal Items," highlight the importance of rehearsal in memory.

John Thibaut and Harold Kelley publish *The Social Psychology of Groups.*

1960 George Sperling publishes "The Information Available in Brief Visual Presentations."

1961 Georg von Békésy receives a Nobel Prize for research on the physiology of hearing.

David McClelland publishes *The Achieving Society.*

1962 Jerome Kagan and Howard Moss publish *Birth to Maturity.*

Martha E. Bernal becomes the first Latina to earn a U.S. doctoral degree (Ph.D. in clinical psychology, Indiana University).

Martha E. Bernal
(1931–2001)

Stanley Schachter and Jerome Singer publish findings that support the two-factor theory of emotion.

Albert Ellis' *Reason and Emotion in Psychotherapy* is published; it is a milestone in the development of rational-emotive therapy (RET).

1963 Stanley Milgram's "Behavioral Study of Obedience" appears in the *Journal of Abnormal and Social Psychology.*

1964

Marigold Linton becomes the first Native American to receive a doctoral degree in psychology (University of California, Los Angeles). She is a founding member of both the Society for Advancement of Chicanos and Native Americans in Science, and the National Indian Education Association.

Marigold Linton
(born 1936)

1965 Canadian researcher Ronald Melzack and British researcher Patrick Wall propose the gate-control theory of pain.

The Archives of the History of American Psychology is founded at the University of Akron.

All Portraits: Macmillan Learning

1966 Nancy Bayley becomes the first woman to receive the APA's Distinguished Scientific Contribution Award.

Jerome Bruner and colleagues at Harvard University's Center for Cognitive Studies publish *Studies in Cognitive Growth*.

William Masters and Virginia Johnson publish results of their research in *Human Sexual Responses*.

Allen Gardner and Beatrix Gardner begin training a chimpanzee named Washoe in American Sign Language at the University of Nevada, Reno. (Washoe dies in 2007.)

John Garcia
(1917–1983)

John Garcia and Robert Koelling publish a study on taste aversion in rats.

David M. Green and John A. Swets publish *Signal Detection Theory and Psychophysics*.

Julian Rotter publishes research on locus of control.

1967 Publication of Ulric Neisser's *Cognitive Psychology*, which helps to steer psychology away from behaviorism and toward cognitive processes.

Martin Seligman and Steven Maier publish the results of their research on "learned helplessness" in dogs.

1968 Richard Atkinson and Richard Shiffrin's influential three-stage memory model appears in *The Psychology of Learning and Motivation*.

Neal E. Miller's article in *Science*, describing instrumental conditioning of autonomic responses, stimulates research on biofeedback.

1969 Albert Bandura publishes *Principles of Behavior Modification*.

The Association for Women in Psychology is founded. E. Kitch Childs is instrumental in this effort, pioneering therapy techniques grounded in "intersectionality" (considering how race, class, and other aspects of identity may combine to create discrimination or disadvantage).

George Miller, in his APA presidential address, "Psychology as a Means of Promoting Human Welfare," emphasizes the importance of "giving psychology away."

1970

Reiko Homma True
(born 1933)

Psychologist Reiko Homma True lobbies successfully to open the Asian American Community Mental Health program—the first to focus on a minority population.

1971

Kenneth B. Clark
(1914–2005)

Kenneth B. Clark becomes the first Black president of the APA. He spends his career studying racial bias in schools. His research helps desegregate U.S. schools and leads the federal government to prioritize spending to improve Black children's educational experiences.

Albert Bandura publishes *Social Learning Theory*.

B. F. Skinner publishes *Beyond Freedom and Dignity*.

1972 Elliot Aronson publishes *The Social Animal*.

Fergus Craik and Robert Lockhart's "Levels of Processing: A Framework for Memory Research" appears in the *Journal of Verbal Learning and Verbal Behavior*.

Robert Rescorla and Allan Wagner publish their associative model of Pavlovian conditioning.

Derald Wing Sue
(born 1942)

Stanley Sue
(born 1944)

Under the leadership of Derald Wing Sue and Stanley Sue, the Asian American Psychological Association is founded.

1973 APA votes to remove "homosexuality" as a psychological disorder from the *Diagnostic and Statistical Manual of Mental Disorders*.

Ethologists Karl von Frisch, Konrad Lorenz, and Nikolaas Tinbergen receive the Nobel Prize for their research on animal behavior.

1974 APA's Division 2 first publishes its journal, *Teaching of Psychology*, with Robert S. Daniel as editor.

Eleanor Maccoby and Carol Jacklin publish *The Psychology of Sex Differences*.

1975 Biologist Edward O. Wilson's *Sociobiology* is published; it will be a controversial precursor to evolutionary psychology.

1976 Sandra Wood Scarr and Richard A. Weinberg publish "IQ Test Performance of Black Children Adopted by White Families" in *American Psychologist*.

Robert V. Guthrie
(1930–2005)

Psychologist Robert V. Guthrie publishes *Even the Rat Was White*, the first history of Black psychologists in the U.S.

Saundra Murray Nettles chairs the Task Force on Black Women's Priorities, which leads to the creation of APA's Division 35, Section 1: The Psychology of Black Women.

Psychologist Carolyn Payton becomes Director of the U.S. Peace Corps, the first woman and the first Black person to serve in that role.

1978 Psychologist Herbert A. Simon, Carnegie-Mellon University, wins a Nobel Prize for pioneering research on computer simulations of human thinking and problem solving.

All Portraits: Macmillan Learning

1979 James J. Gibson publishes *The Ecological Approach to Visual Perception*.

Elizabeth Loftus publishes *Eyewitness Testimony*, showing that eyewitness memory is often inaccurate.

1981 David Hubel and Torsten Wiesel receive a Nobel Prize for research on single-cell recordings that identified feature detector cells in the visual cortex.

Roger Sperry receives a Nobel Prize for research on split-brain patients.

U.S. sociologist Harriette Pipe McAdoo publishes *Black Families*, an anthology of work done with John Lewis McAdoo on middle class Black families. Previous studies had focused on dysfunctional families, such as those in contact with prison and drug treatment programs.

Paleontologist Stephen Jay Gould publishes *The Mismeasure of Man*, highlighting the debate concerning biological determination of intelligence.

1983 In his *Frames of Mind*, Howard Gardner outlines his theory of multiple intelligences.

1984 44 Society for the Psychology of Sexual Orientation and Gender Diversity — The APA creates Division 44 (Society for the Psychology of Sexual Orientation and Gender Diversity).

1987 Elizabeth Scarborough and Laurel Furumoto publish *Untold Lives: The First Generation of American Women Psychologists*.

Fluoxetine (Prozac) is introduced as a treatment for depression.

Wilbert J. McKeachie, University of Michigan, receives the first APA Award for Distinguished Career Contributions to Education and Training in Psychology.

1988 The American Psychological Society is founded. The organization changes its name to the Association for Psychological Science in **2006.**

1990 Psychiatrist Aaron Beck receives the Distinguished Scientific Award for the Applications of Psychology for advancing understanding and treatment of psychopathology, including pivotal contributions to the development of cognitive therapy.

B. F. Skinner receives APA's first Citation for Outstanding Lifetime Contributions to Psychology and presents his last public address, "Can Psychology Be a Science of Mind?" (He died a few days later at age 86.)

1991 Martin Seligman publishes *Learned Optimism*, which foreshadows the "positive psychology" movement.

1992 Teachers of Psychology in Secondary Schools (TOPSS) is established as part of the APA.

About 3000 U.S. secondary school students take the first Advanced Placement (AP) Examination in Psychology.

1993 Psychologist Judith Rodin is elected president of the University of Pennsylvania, becoming the first female president of an Ivy League school.

1996 Dorothy Cantor becomes the first president of the APA with a Psy.D. degree.

1998 *The Handbook of Asian American Psychology* is published.

2002 New Mexico becomes the first U.S. state to allow qualified clinical psychologists to prescribe certain drugs. Many U.S. states now allow nurse practitioners and other providers to prescribe psychiatric medication.

Psychologist Daniel Kahneman, Princeton University, receives a Nobel Prize for research on decision making later summarized in his **2011** book, *Thinking Fast and Slow*.

2009 Psychologist Judy Chu becomes the first Chinese American woman elected to the U.S. Congress.

2011 Proposed by participants at the 2008 national conference at the University of Puget Sound, the document "Principles for Quality Undergraduate Education in Psychology," is approved as official APA policy.

Melba J. T. Vasquez becomes the first Latina president of the APA.

Melba J. T. Vasquez (born 1951)

2013 U.S. President Barack Obama announces $100 million in funding for an interdisciplinary project to advance understanding of the human brain.

2015 The *Independent Review Relating to APA Ethics Guidelines, National Security Interrogations, and Torture* is presented to the APA.

2018 Kristina Olson becomes the first psychologist to receive the National Science Foundation's Waterman Award. She also receives a 2018 MacArthur Fellowship for her work studying the social and cognitive development of transgender and gender-nonconforming youth.

2020 MacArthur Fellowship awardee and implicit bias researcher Jennifer L. Eberhardt receives multiple awards for authoring *Biased: Uncovering the Hidden Prejudice That Shapes What We See, Think, and Do.*

Cognitive neuroscientist Damien Fair wins a MacArthur award for his work studying neurodiverse children.

2021 The APA issues an official "Apology to People of Color for APA's Role in Promoting, Perpetuating, and Failing to Challenge Racism, Racial Discrimination, and Human Hierarchy in the U.S."

All Portraits: Macmillan Learning

Appendix B

Career Fields in Psychology

Jennifer Zwolinski, *University of San Diego*

What can you do with a degree in psychology? Lots!

As a psychology major, you will graduate with a scientific mindset and an awareness of basic principles of human behavior (biological mechanisms, nature–nurture interactions, life-span development, cognition, psychological disorders, social interaction). This background will prepare you for success in many areas, including business, the helping professions, health services, marketing, law, sales, and teaching. You may even go on to graduate school for specialized training to become a psychology professional. This appendix provides an overview of some of psychology's key career fields, most of which require a graduate degree in psychology.[1] For an expanded discussion, see ***Pursuing a Psychology Career*** in Achieve, where you can learn more about the many interesting options available to those with bachelor's, master's, and doctoral degrees in psychology. You can also read about the professional skills and abilities a psychology major (or even psychology

coursework, if you are a non-major) can provide, how to articulate those skills and abilities to potential employers, and other steps you can take to help you secure a job after graduation.

If you are like most psychology students, you may be unaware of the wide variety of specialties and work settings available in psychology (Terre & Stoddart, 2000). To date, the American Psychological Association (APA) has 54 divisions that represent the popular subfields and interest groups of APA members (TABLE B.1). APA Division 2 (Society for the Teaching of Psychology) offers an excellent career exploration resource for those interested in learning about the hundreds of career options available for students with an undergraduate degree in psychology.

TABLE B.1 APA Divisions by Number and Name

1. Society for General Psychology
2. Society for the Teaching of Psychology
3. Society for Experimental Psychology and Cognitive Science
4. *There is no active Division 4*.
5. Quantitative and Qualitative Methods
6. Society for Behavioral Neuroscience and Comparative Psychology
7. Developmental Psychology
8. Society for Personality and Social Psychology
9. Society for the Psychological Study of Social Issues (SPSSI)
10. Society for the Psychology of Aesthetics, Creativity and the Arts
31. State, Provincial and Territorial Psychological Association Affairs
32. Society for Humanistic Psychology
33. Intellectual and Developmental Disabilities/Autism Spectrum Disorder
34. Society for Environmental, Population and Conservation Psychology
35. Society for the Psychology of Women
36. Society for the Psychology of Religion and Spirituality
37. Society for Child and Family Policy and Practice
38. Society for Health Psychology
39. Society for Psychoanalysis and Psychoanalytic Psychology

11. *There is no active Division 11*.
12. Society of Clinical Psychology
13. Society of Consulting Psychology
14. Society for Industrial and Organizational Psychology
15. Educational Psychology
16. School Psychology
17. Society of Counseling Psychology
18. Psychologists in Public Service
19. Society for Military Psychology
20. Adult Development and Aging
21. Applied Experimental and Engineering Psychology
22. Rehabilitation Psychology
23. Consumer Psychology
24. Society for Theoretical and Philosophical Psychology
25. Behavior Analysis
26. Society for the History of Psychology
27. Society for Community Research and Action: Division of Community Psychology
28. Psychopharmacology and Substance Abuse
29. Society for the Advancement of Psychotherapy
30. Society of Psychological Hypnosis
40. Society for Clinical Neuropsychology
41. American Psychology-Law Society
42. Psychologists in Independent Practice
43. Society for Couple and Family Psychology
44. Society for the Psychology of Sexual Orientation and Gender Diversity
45. Society for the Psychological Study of Culture, Ethnicity and Race
46. Society for Media Psychology and Technology
47. Society for Sport, Exercise and Performance Psychology
48. Society for the Study of Peace, Conflict and Violence: Peace Psychology Division
49. Society of Group Psychology and Group Psychotherapy
50. Society of Addiction Psychology
51. Society for the Psychological Study of Men and Masculinities
52. International Psychology
53. Society of Clinical Child and Adolescent Psychology
54. Society of Pediatric Psychology
55. Society for Prescribing Psychology
56. Trauma Psychology

Information from: American Psychological Association (2020).

The following paragraphs (arranged alphabetically) describe some of psychology's main career fields.

Biological Psychologists

Biological psychologists seek to understand and explain how biological and psychological processes influence behavior. Biological psychologists typically use advanced technologies in research settings with human participants or animals to investigate the influence of biological factors on sensation, learning, memory, motivation, and emotion. Although many biological psychologists work in academic research or teaching environments, the interdisciplinary nature of their training prepares them to work in various other settings, including private consulting, public or government health, and the pharmaceutical, biotechnology, or medical industries. Subfields of biological psychology include neuropsychology, behavioral neuroscience, and cognitive neuroscience.

Clinical Psychologists

Clinical psychologists promote psychological health in individuals, groups, and organizations. Some clinical psychologists specialize in specific psychological disorders. Others treat a range of disorders, from adjustment difficulties to severe psychopathology. Clinical psychologists often provide therapy but may also engage in research, teaching, assessment, and consultation. Clinical psychologists work in a variety of settings, including private practice, mental health service organizations, schools, universities, industry, legal systems, medical systems, counseling centers,

government agencies, correctional facilities, nonprofit organizations, and military services.

To become a clinical psychologist, you will need to earn a doctorate from a clinical psychology program. The APA sets the standards for clinical psychology graduate programs, offering *accreditation* (official recognition) to those who meet their standards. To serve clients representing a variety of races, ethnicities, genders, ages, socioeconomic backgrounds, sexual orientations, and physical abilities, the APA also encourages professional psychologists to seek ongoing diversity training throughout their careers. In all U.S. states, clinical psychologists working in independent practice must obtain a license to offer services such as therapy and testing.

Cognitive Psychologists

Cognitive psychologists study thought processes and focus on such topics as perception, language, attention, problem solving, memory, judgment and decision making, and intelligence. Research interests include designing computer-based models of thought processes and identifying biological correlates of cognition. As a cognitive psychologist, you might work as a professor, industrial consultant, or human factors specialist in an educational or business setting.

iStock/Getty Images

Cognitive consulting Cognitive psychologists may advise businesses on how to operate more effectively by understanding the human factors involved.

Community Psychologists

Community psychologists move beyond focusing on specific individuals or families and deal with broad problems of mental health in community settings. These psychologists believe that human behavior is powerfully influenced by the interaction between people and their physical, social, political, and economic environments. Community psychologists value the uniqueness of individuals, communities, and social groups, and they actively integrate their clients' diverse backgrounds into their work. With this understanding and appreciation, they seek to promote psychological health by enhancing environmental settings—focusing on preventive measures and crisis intervention, with special attention to the problems of underserved and underrepresented groups. Many community psychologists

collaborate with professionals in other areas, such as public health, with a shared emphasis on prevention. As a community psychologist, your work settings could include federal, state, and local departments of mental health, corrections, and welfare. You might conduct research or help evaluate research in health service settings, serve as an independent consultant for a private or government agency, or teach and consult as a college or university faculty member.

AP Photo

Community care Community psychologists have helped people in Haiti to work through the ongoing emotional challenges that come with enduring repeated natural disasters.

Counseling Psychologists

Counseling psychologists help people adjust to life transitions or make lifestyle changes. Although similar to clinical psychologists, counseling psychologists typically help people with adjustment problems rather than severe psychopathology. Like clinical psychologists, counseling psychologists conduct therapy and provide assessments to individuals and groups. As a counseling psychologist, you would likely emphasize your clients' strengths, helping them to use their own skills, interests, and abilities to cope during transitions. You might find yourself working in an academic setting as a faculty member or administrator or in a university counseling center, community mental health center, business, or private practice. As with clinical psychology, if you plan to work in independent practice you will need to obtain a state license to provide counseling services to the public. And, as is the case for clinical psychology, the APA promotes diversity and cultural awareness and competencies across all phases of career development—from graduate training to continuing education after licensure.

Developmental Psychologists

Developmental psychologists conduct research on age-related behavioral changes and apply their scientific knowledge to educational, child-care, policy, and related settings. As a

developmental psychologist, you would investigate change across a broad range of topics, including the biological, psychological, cognitive, and social aspects of development. Developmental psychology informs a number of applied fields, including educational psychology, school psychology, child psychopathology, and gerontology. This field also informs public policy in areas such as education and child-care reform, maternal and child health, and attachment and adoption. You would probably specialize in a specific stage of the life span, such as infancy, childhood, adolescence, or middle or late adulthood. Your work setting could be an educational institution, day-care center, youth group program, or senior center.

Educational Psychologists

Educational psychologists are interested in the psychological processes involved in learning. They study the relationship between learning and physical and social environments, and they develop strategies for enhancing the learning process. As an educational psychologist working in a university psychology department or school of education, you might conduct basic research on topics related to learning, or develop innovative methods of teaching to enhance the learning process. You might design effective tests, including measures of aptitude and achievement. You might be employed by a school or government agency or charged with designing and implementing effective employee-training programs in a business setting.

Environmental Psychologists

Environmental psychologists study the interaction of individuals with their natural and built (urban) environments. They are interested in how we influence and are affected by these environments. As an environmental psychologist, you might study wildlife conservation, the impact of urbanization on health, or cognitive factors involved in sustainable lifestyle choices. Environmental psychologists tend to address these kinds of issues by working with other professionals as part of an interdisciplinary team. As an environmental psychologist, you might work in a consulting firm, an academic setting, the nonprofit sector, or the government.

Experimental Psychologists

Experimental psychologists are a diverse group of scientists who investigate a variety of basic behavioral processes in humans and other animals. Prominent areas of experimental research include comparative methods of science, motivation, learning, thought, attention, memory, perception, and language. Most experimental psychologists identify with a particular subfield, such as cognitive psychology, depending on their interests and training. Experimental research methods are not limited to the field of experimental psychology; many other subfields rely on experimental methodology to conduct studies. As an experimental psychologist, you would most likely work in an academic setting, teaching courses

and supervising students' research in addition to conducting your own research. Or you might be employed by a research institution, zoo, business, or government agency.

Forensic Psychologists

Forensic psychologists apply psychological principles to legal issues. They conduct research on the interface of law and psychology, help to create public policies related to mental health, help law enforcement agencies in criminal investigations, or consult on jury selection and deliberation processes. They also provide assessment to assist the legal community. Although most forensic psychologists are clinical psychologists, many have expertise in other areas of psychology, such as social or cognitive psychology. Some also hold law degrees. As a forensic psychologist, you might work in a university psychology department, law school, research organization, community mental health agency, law-enforcement agency, court, or correctional setting.

Rick Wood/Milwaukee Journal-Sentinel/AP Photo

Forensics in court Forensic psychologists may be called on to assist police officers who are investigating a crime scene, but most forensic work occurs in the lab and for the judicial system.

Health Psychologists

Health psychologists are researchers and practitioners concerned with psychology's contribution to promoting health and preventing disease. As applied psychologists or clinicians, they may help individuals lead healthier lives by designing, conducting, and evaluating programs to stop smoking, lose weight, improve sleep, manage pain, prevent the spread of sexually transmitted infections, or treat psychosocial problems associated with chronic and terminal illnesses. As researchers and clinicians, they identify conditions and practices associated with health and illness to help create effective interventions. In public service, health psychologists study and work to improve government policies and health care systems. As a health psychologist, you could be employed in a hospital, medical school, rehabilitation center, public health agency, college or university, or, if you are also a clinical psychologist, in private practice.

Industrial-Organizational (I/O) Psychologists

Industrial-organizational psychologists study the relationship between people and their working environments. They may develop new ways to increase productivity, improve personnel selection, or promote job satisfaction in an organizational setting. Their interests include organizational structure and change, consumer behavior, and personnel selection and training. As an I/O psychologist, you might conduct workplace training or provide organizational analysis and development. You may find yourself working in business, industry, the government, or a college or university. Or you may be self-employed as a consultant or work for a management consulting firm. (For more on I/O psychology, see Appendix C, Psychology at Work.)

Neuropsychologists

Neuropsychologists investigate the relationship between neurological processes (structure and function of the brain and nervous system) and behavior. As a neuropsychologist you might assess, diagnose, or treat central nervous system disorders, such as Alzheimer's disease or stroke. You might also evaluate individuals for evidence of head injuries; specific learning disorders; and neurodevelopmental disorders, such as autism spectrum disorder and attention-deficit/hyperactivity disorder (ADHD). If you are a

clinical neuropsychologist, you might work in a hospital's neurology, neurosurgery, or psychiatric unit. Neuropsychologists also work in academic settings, where they conduct research and teach.

Personality Psychologists

Personality psychologists study how individuals differ in their feelings, thoughts, motivations, and behaviors. Because their interests are complementary, personality psychologists and social psychologists often collaborate to understand how both individual and social factors impact phenomena such as romantic attraction, persuasion, prosocial behavior, and conformity. As a personality psychologist, you would probably be a researcher or college or university faculty member. Your research might take place in a laboratory, clinic, or field setting, and your work might focus on factors that impact personality development or how personality is related to other areas, such as law, business, or education. You might also work in the private sector, as a consultant to businesses, or in a public nonprofit organization.

Psychometric and Quantitative Psychologists

Psychometric and quantitative psychologists study the methods and techniques used to acquire psychological knowledge. A psychometric psychologist may update existing neurocognitive or

personality tests, or devise new tests for use in clinical settings, in schools and other institutional settings, and in business and industry. These psychologists also administer, score, and interpret such tests. Quantitative psychologists collaborate with researchers to design, analyze, and interpret the results of research programs. As a psychometric or quantitative psychologist, you would need to be well trained in research methods, statistics, and computational software. You would most likely be employed by a university or college, a testing company, a private research firm, or a government agency.

amriphoto/Getty Images

Evaluating cognitive functioning The APA projects that by 2030, those age 65 and older will be the U.S. age group requiring the most psychological care (APA, 2018). Psychologists can

use neuropsychological assessments to evaluate cognitive capacities, helping to diagnose, treat, and manage psychological disorders such as Alzheimer's disease.

Rehabilitation Psychologists

Rehabilitation psychologists are researchers and practitioners who work with people who have lost optimal functioning after an accident, illness, or other event. As a rehabilitation psychologist, you would probably work in a medical rehabilitation facility or hospital. You might also work in a medical school, university, or government vocational rehabilitation agency, or in private practice serving people with physical disabilities.

School Psychologists

School psychologists are involved in the assessment of and intervention for children in educational settings. They diagnose and treat cognitive, social, and emotional problems that may negatively influence children's learning or overall functioning at school. As a school psychologist, you would collaborate with teachers, parents, and administrators, making recommendations to improve student learning. You might work at a school or child guidance center, for a government agency, or at a behavioral research laboratory.

© Spencer Grant/PhotoEdit

Assessing and supporting children School psychologists may find themselves working with children individually or in groups. They receive interdisciplinary training in mental health assessment and behavior analysis, research methods and design, and special needs education. They work primarily in schools, but also in a range of other settings.

Social Psychologists

Social psychologists are interested in our interactions with others. Social psychologists study how our beliefs, feelings, and behaviors are affected by and influence other people. They study topics such as attitudes, aggression, prejudice, interpersonal attraction, group

behavior, and leadership. In an initiative to use social psychological and personality research to address social problems, APA's Division 8 (Society for Personality and Social Psychology) has established a frequently updated repository of research, videos, and other resources to increase public awareness of racism, bias, and diversity in general. As a social psychologist, you would probably be a college or university faculty member. You might also work in organizational consultation, market research, or other applied psychology fields, including social neuroscience. Some social psychologists work for hospitals, government agencies, social networking sites, or businesses performing applied research.

Sport Psychologists

Sport psychologists study the psychological factors that influence, and are influenced by, participation in sports and other physical activities. Their professional activities include coach education and athlete preparation, as well as research and teaching. Sport psychologists who also have a clinical or counseling degree can apply those skills to working with individuals with psychological problems, such as anxiety or substance use disorder, that might interfere with optimal performance. As a sport psychologist, if you were not working in an academic or research setting, you would most likely work as part of a team or an organization, or in a private capacity.

Improving athletic achievement Sussex cricket player Stuart Meaker gathers input from sport psychologist Rebecca Symes during warmup.

* * *

The next time someone asks you what you will do with your psychology degree, tell them you have lots of options. You might use your acquired skills and understanding to get a job and succeed in any number of fields, or you might pursue graduate school and then career opportunities in associated professions. In any case, what you have learned about behavior and mental processes will surely enrich your life (Hammer, 2003).

For many people, to live is to work. Work supports us, enabling food, water, and shelter. Work connects us, meeting our social needs. Work helps define us. Meeting people and wondering about their identity, we may ask, “So, what do you do?”

We vary in our job satisfaction: On the day we leave the workforce, some of us will sadly bid our former employer farewell, while others will gladly bid

them good riddance. We vary in the predictability of our career path: We will change jobs, some of us often, for a variety of reasons—cutbacks, a desire for better work-life balance, or to pursue a passion project. And we vary in how we view our work as a way to earn a paycheck or to pursue a meaningful calling, an opportunity to do the bare minimum or to maximize our potential. Let's take a look at how psychologists can help explain these differences.

The jobs people do: Columnist Gene Weingarten (2002) noted that sometimes a humorist knows "when to just get out of the way." Here are some sample self-reported job titles from the U.S. Department of Labor: animal impersonator, human projectile, banana ripening-room supervisor, impregnator, impregnator helper, dope sprayer, finger waver, rug scratcher, egg smeller, bottom buffer, cookie breaker, brain picker, hand pouncer, bosom presser, and mother repairer.

Work and Life Satisfaction

People across various occupations vary in their attitudes toward their work. Some view their work as a *job,* a possibly unfulfilling but necessary way to make money. Others view their work as a *career,* an opportunity to advance from one position to a better position. The rest—those who view their work as a *calling,* a fulfilling and socially useful activity—report the highest satisfaction with their work and with their lives (Dik & Duffy, 2012; Wrzesniewski & Dutton, 2001).

> **"Some people have *jobs.* Some people have *careers*.... When you've got a career, there ain't enough time in the day.... When you've got a job, there's too much time."** — Comedian Chris Rock

Flow at Work

Learning Objective Question LOQ C-1

What is *flow?*

The work satisfaction findings would not have surprised Mihaly Csikszentmihalyi [chick-SENT-me-hi] (1934–2021). He observed that our quality of life increases when we are purposefully engaged.

Between the anxiety of being overwhelmed and stressed, and the apathy of being underwhelmed and bored, lies the experience of **flow** (Csikszentmihalyi, 1990, 1999). "Flow," Csikszentmihalyi noted, "occurs in that delicate zone between anxiety and boredom" (Goleman, 1986). We might experience it when we clean a kitchen, organize a spreadsheet, or read a psychology text. (Are you experiencing flow right now?) Perhaps you can recall being in a zoned-out flow state while scrolling social media.

Csikszentmihalyi formulated the flow concept after studying artists who spent hour after hour painting or sculpting with focused concentration. Immersed in a project, they worked as if nothing else mattered, and then, when finished, they promptly moved on. The artists seemed driven less by external rewards—money, praise, promotion—than by the intrinsic rewards of creating their art. Nearly 200 other studies confirm that *intrinsic motivation* enhances performance (Cerasoli et al., 2014).

Csikszentmihalyi studied dancers, chess players, surgeons, writers, parents, mountain climbers, sailors, and farmers. His research included Australian, North American, Korean, Japanese, and Italian participants, who ranged in age from the teen years to the golden years. A clear principle emerged: It's exhilarating to flow with an activity that fully engages our skills (Fong et al., 2015). Flow experiences boost our sense of self-esteem, competence, and well-being. One research team studying 10,000 Swedes found that frequent

flow experiences reduced their risk of depression and burnout (Mosing et al., 2018). A focused mind is a happy mind.

> Have you ever noticed that when you are immersed in an activity, time flies? And that when you are watching the clock, it seems to move more slowly? French researchers have confirmed that the more we attend to an event's duration, the longer it seems to last (Couli et al., 2004).

Idleness may sound like bliss. You may dream of a future filled with streaming movies, sleeping in, and no responsibilities. In reality, purposeful work enriches our lives. People who leave the workforce tend to become unhappy, but rejoining the workforce rapidly improves their mood (Y. Zhou et al., 2019). Busy people are often happy people (Hsee et al., 2010; Robinson & Martin, 2008).

Jacob Ammentorp Lund/iStock/Getty Images

Attention theft It takes energy to resist checking our phones, and time to refocus mental concentration after each disruption. Such frequent interruptions disrupt flow. A solution: Disable notifications, and check the phone only during scheduled breaks.

Finding Your Own Flow, and Matching Interests to Work

Want to identify your own path to flow? You can start by pinpointing your strengths and the types of work that may prove satisfying and successful. Marcus Buckingham and Donald Clifton (2001) suggested asking yourself four questions:

1. What activities give me pleasure? Bringing order out of chaos? Playing host? Helping others? Challenging sloppy thinking?
2. What activities leave me wondering, "When can I do this again?" rather than, "When will this be over?"
3. What sorts of challenges do I relish? And which do I dread?
4. What sorts of tasks do I learn easily? And which do I struggle with?

You may find your skills engaged and time flying when teaching or selling or writing or cleaning or consoling or creating or repairing. If an activity feels good, if it comes easily, if you look forward to it, then look deeper. You'll see your strengths at work (Buckingham, 2007). For a free (requires registration) assessment of your own strengths, take the "Brief Strengths Test" at tinyurl.com/AssessStrengths.

The U.S. Department of Labor also offers a career interest questionnaire through its Occupational Information Network (O*NET). At MyNextMove.org/explore/ip you will need about 10 minutes to respond to 60 items, indicating how much you would like or dislike activities ranging from building kitchen cabinets to playing

a musical instrument. You will then receive feedback on how strongly your responses reflect six interest types (Holland, 1996):

- ***Realistic*** (hands-on doers)
- ***Investigative*** (thinkers)
- ***Artistic*** (creators)
- ***Social*** (helpers, teachers)
- ***Enterprising*** (persuaders, deciders)
- ***Conventional*** (organizers)

Finally, depending on how much training or schooling you are willing to complete, you will be shown occupations that fit your interest pattern (selected from a national database of 900+ occupations).

Do what you love and you will love what you do. Career counseling science aims, first, to assess people's differing values, personalities, and, especially, *interests,* which are remarkably stable and predictive of future life choices and outcomes (Hanna & Rounds, 2020). (Your job may change, but your interests today will likely still be your interests in 10 years.) Second, it aims to alert people to well-matched vocations —vocations with a good *person-environment fit.* It pays to have a job that fits your personality. People high in openness earn more if they hold jobs that demand openness; people who are highly extraverted earn more if they work in jobs that require extraversion (Denissen et al., 2018).

"Find a job you love, and you'll never work another day of your life." — Popular saying expressed in a Facebook hiring video, 2016

One study assessed 400,000 high school students' interests and then followed the students over time. The take-home finding: "Interests uniquely predict academic and career success over and above cognitive ability and personality" (Rounds & Su, 2014). Sixty other studies confirm the point both for students in school and workers on the job: Interests predict both performance and persistence (Nye et al., 2012). Lack of job fit can fuel frustration, resulting in unproductive and even hostile work behavior (Harold et al., 2016). *Industrial-organizational psychologists* put career counseling science into action. First, they use surveys to assess people's interests, values, personalities, and workplace culture preferences. Next, they use the data to suggest occupations and connect respondents with job listings.

Michael Maslin/The Cartoon Bank

"Let's face it: you and this organization have never been a good fit."

Ask Yourself

What have you discovered about your own strengths and about the kind of career you might see yourself pursuing?

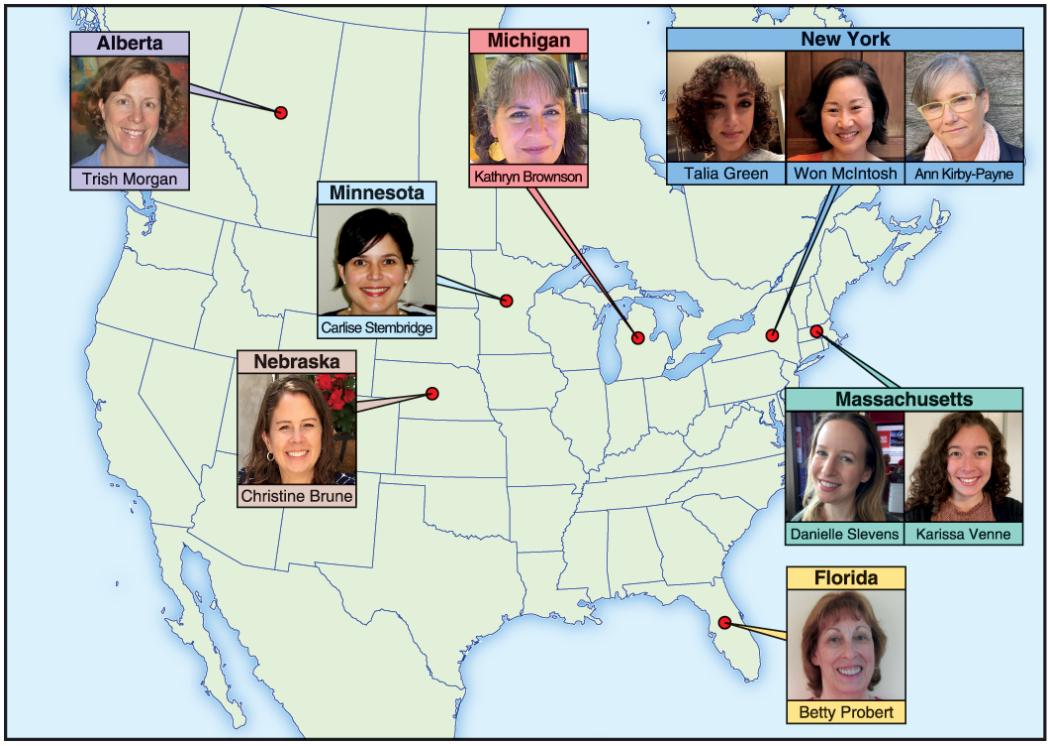
Retrieval Practice

RP-1 What is the value of finding flow in our work?

ANSWERS IN APPENDIX E

Industrial-Organizational Psychology

LOQ C-2



What are industrial-organizational psychology's three key areas of study?

In developed nations, work has expanded, from farming to manufacturing to *knowledge work*. More and more work is outsourced to temporary employees and consultants, or to workers telecommuting from off-site workplaces (Gallup, 2020). (The three-author team for this book and its teaching package is aided immeasurably by a team of people across North America, from Alberta to Florida.)

The Covid pandemic dramatically increased remote work and virtual teamwork. This raised new issues for I/O psychologists to study (Kniffin et al., 2021):

- How will remote work affect workers' attitudes toward their employer and co-workers?
- How does remote versus in-person work affect workers' well-being?

- How can leaders best communicate with and mentor remote workers?
- How can remote work inclusively support and connect workers of all ages, abilities, cultural backgrounds, and ethnicities?

Collaboration across the miles The editorial and production team that guides the development of this book and its resources works from far-flung places across North America.

As work has changed, have our attitudes toward our work also changed? Has our satisfaction with work increased or decreased? Has the *psychological contract*—the sense of mutual obligation between workers and employers—become more or less trusting and secure? How can psychologists help organizations make work more

satisfying and productive? These are among the questions that fascinate **industrial-organizational (I/O) psychologists** as they apply psychology's principles to the workplace (**TABLE C.1**).

- The I/O psychology subfield of **personnel psychology** applies psychology's methods and principles to selecting, placing, training, and evaluating workers. Personnel psychologists match people with jobs by identifying and placing well-suited candidates.
- The **organizational psychology** subfield considers how work environments and management styles influence worker motivation, satisfaction, and productivity. It focuses on modifying jobs and supervision in ways that boost morale and productivity.
- **Human factors psychology**, a distinct field allied with I/O psychology, explores how machines and environments can be optimally designed to fit human abilities. Human factors psychologists study people's natural perceptions and inclinations, using this research to create user-friendly machines and work settings.

TABLE C.1 I/O Psychology and Human Factors Psychology at Work

As scientists, consultants, and management professionals, industrial-organizational (I/O) psychologists may be found helping organizations to resolve work-family conflicts, build employee retention, improve organizational spirit, or promote teamwork. Human factors psychologists also contribute to human safety and improved designs.

Personnel Psychology: Maximizing Human Potential

Developing training programs to increase job seekers' success

Selecting and placing employees

- Developing and testing assessment tools for selecting, placing, and promoting workers
- Analyzing job content
- Optimizing worker placement

Training and developing employees

- Identifying needs
- Designing training programs, including for ethical and diverse workplaces
- Evaluating training programs

Appraising performance

- Developing guidelines
- Measuring individual performance
- Measuring organizational performance

Organizational Psychology: Building Better Organizations

Developing organizations

- Analyzing organizational structures
- Maximizing worker satisfaction and productivity
- Facilitating organizational change

Enhancing quality of work life

- Expanding individual productivity
- Identifying elements of satisfaction
- Redesigning jobs
- Balancing work and nonwork life in an era of social media, smartphones, and rapid technological change

Human Factors Psychology: Optimizing Machines and Environments

- Designing optimal work environments
- Optimizing person-machine interactions
- Developing systems technologies

Personnel Psychology

LOQ C-3

How do personnel psychologists facilitate job seeking, employee selection, work placement, and performance appraisal?

Psychologists assist organizations at various stages of selecting and assessing employees. They may help identify needed job skills, develop effective selection methods, recruit and evaluate diverse applicants, introduce and train new employees, appraise performance, and facilitate team building among people with differing cultural backgrounds. They also seek to enhance the well-being and productivity of *neurodiverse* workers—those on the autism spectrum, or those challenged by ADHD, a learning disorder, or brain injury (Weinberg & Doyle, 2017).

Psychologists also assist job seekers. Across four dozen studies, training programs (which teach job-search skills, improve self-presentation, boost self-confidence, promote goal setting, and enlist support) have nearly tripled job seekers' success (Liu et al., 2014).

Using Strengths for Successful Selection

As a new AT&T human resources executive, psychologist Mary Tenopyr (1997) was assigned to solve a problem: Customer-service representatives were failing at a high rate. After concluding that many of the hires were ill-matched to the demands of their new job, Tenopyr developed a new selection instrument:

1. She asked new applicants to respond to various test questions (without as yet making any use of their responses).
2. She followed up later to assess which of the applicants excelled on the job.
3. She identified the earlier test questions that best predicted success.

The happy result of her data-driven work was a new test that enabled AT&T to identify likely-to-succeed representatives. Personnel selection techniques such as this one aim to recruit people with strengths that will enable them and their organization to flourish. Marry the strengths of people with the tasks of organizations and the results are often prosperity, profit, and pleased employees.

Do Interviews Predict Performance?

Employee selection usually includes an interview, and many interviewers feel confident of their ability to predict long-term job performance from a get-acquainted *(unstructured)* interview. What's

therefore shocking is how error-prone interviewers' predictions may be when predicting job or graduate school success. General mental ability has been a better predictor, especially for complex jobs—for which it indicates people's ability to learn new skills (Schmidt & Hunter, 2004; Warne, 2020). Informal interviews are less informative than aptitude tests, work samples, job knowledge tests, and past job performance. After studying thousands of informal interviews and later job success, Google found "zero relationship. It's a complete random mess" (Bock, 2013).

Unstructured Interviews and the Interviewer Illusion

Traditional, unstructured interviews can provide a sense of someone's personality—their expressiveness, warmth, and verbal ability, for example. But these informal interviews also give interviewees considerable power to control the impression they are making in the interview situation (Barrick et al., 2009). Why, then, do many interviewers have such faith in their ability to discern interviewees' fitness for a job? "I have excellent interviewing skills," I/O psychology consultants often hear, "so I don't need reference checking as much as someone who doesn't have my ability to read people." Overrating one's ability to predict people's futures is called the *interviewer illusion* (Dana et al., 2013; Nisbett, 1987). Five factors explain interviewers' overconfidence:

- ***Interviewers presume that people are what they seem to be in the interview situation.*** An unstructured interview may create a

false impression of a person's behavior toward others in different situations. Some interviewees may feign desired attitudes; others may be nervous. As social psychologists explain, when meeting others, we commit the *fundamental attribution error:* We discount the enormous influence of varying situations and mistakenly presume that what we see is what we will get. But research on everything from chattiness to conscientiousness reveals that how we behave reflects not only our enduring traits, but also the details of the particular situation (such as wanting to impress in a job interview).

- ***Interviewers' preconceptions and moods color how they perceive interviewees' responses*** (Cable & Gilovich, 1998; Macan & Dipboye, 1994). If interviewers instantly like a person who perhaps is similar to themselves (opening the door to unintended racial or gender bias), they may interpret the person's assertiveness as indicating "confidence" rather than "arrogance." If told certain applicants have been prescreened, interviewers are disposed to judge them more favorably. Such interviewers are showing *confirmation bias:* They search for information that supports their preconceptions about a job candidate and ignore or distort contradictory evidence (Skov & Sherman, 1986).
- ***Interviewers judge people relative to those interviewed just before and after them*** (Simonsohn & Gino, 2013). If you are being interviewed for a job or graduate program, hope for a day when the other interviewees have been weak.

- ***Interviewers more often follow the successful careers of those they have hired than the successful careers of those they have rejected.*** This missing feedback prevents interviewers from getting a reality check on their hiring ability.
- ***Interviews disclose the interviewee's good intentions, which are less revealing than habitual behaviors*** (Ouellette & Wood, 1998). Intentions matter. People can change. But the best predictor of our future habits will be our past habits. Educational attainments predict job performance partly because people who have the ability and motivation to show up for school each day and stay on task also tend to show up for work and stay on task (Ng & Feldman, 2009). Wherever we go, we take ourselves along.

Hoping to improve prediction and selection, personnel psychologists have put people in simulated work situations, sought information on past performance, aggregated evaluations from multiple interviews, administered tests, and developed job-specific interviews.

Structured Interviews

Unlike casual conversation aimed at getting a feel for someone, **structured interviews** offer a disciplined method of collecting information. A personnel psychologist may analyze a job, script questions, and train interviewers. The interviewers then ask all

applicants the same questions, in the same order, and rate each applicant on established scales.

In an unstructured interview, someone might ask, “How organized are you?” “How well do you get along with people?” or “How do you handle stress?” Street-smart applicants know how to score high: “Although I sometimes drive myself too hard, I handle stress by prioritizing and delegating, and leaving time for sleep and exercise.”

By contrast, structured interviews pinpoint strengths (attitudes, behaviors, knowledge, and skills) that distinguish high performers in a particular line of work. The process includes outlining job-specific situations and asking candidates to explain how they would handle them, and how they handled similar situations in their prior employment. “Tell me about a time when you were caught between conflicting demands, without time to accomplish both. How did you handle that?” In its interviews, Google has asked, “Give me an example of a time when you solved an analytically difficult problem” (Bock, 2013).

To reduce memory distortions and bias, the interviewer takes notes, makes ratings as the interview proceeds, and avoids irrelevant and follow-up questions. The structured interview therefore feels less friendly, but that can be explained to the applicant: “This conversation won’t typify how we relate to each other in this organization.”

A review of 150 findings revealed that structured interviews had double the predictive accuracy of unstructured interviews (Schmidt & Hunter, 1998; Wiesner & Cronshaw, 1988). Structured interviews also reduce bias, such as against overweight applicants (Kutcher & Bragger, 2004).

If, instead, we let our intuitions bias the hiring process, noted Malcolm Gladwell (2000, p. 86), then "all we will have done is replace the old-boy network, where you hired your nephew, with the new-boy network, where you hire whoever impressed you most when you shook his hand. Social progress, unless we're careful, can merely be the means by which we replace the obviously arbitrary with the not so obviously arbitrary."

To recap, personnel psychologists help train job seekers, and they assist organizations in analyzing jobs, recruiting well-suited applicants, and selecting and placing employees. They also appraise employees' performance (**FIGURE C.1**)—our next topic.

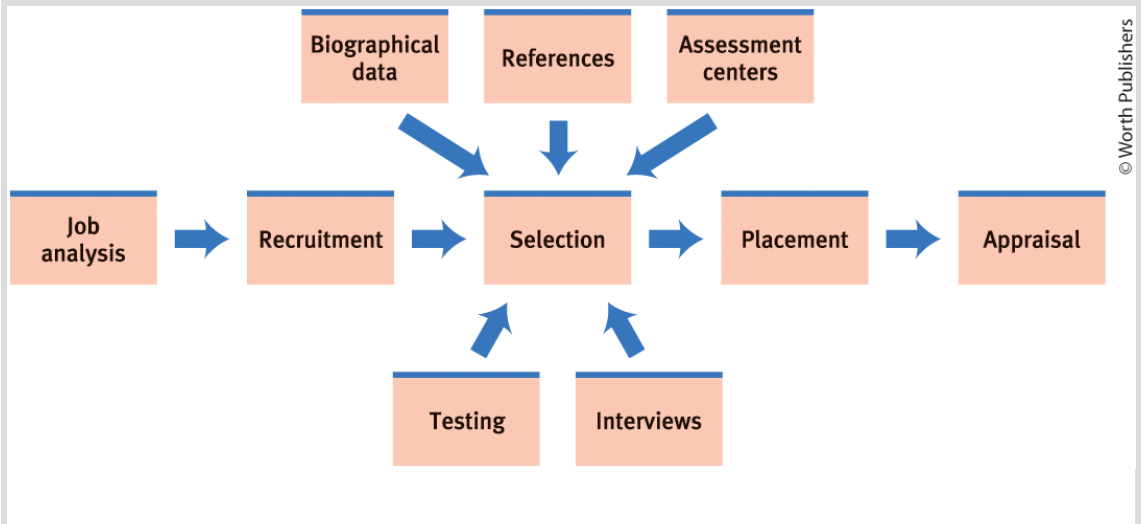

FIGURE C.1 Personnel psychologists at work Personnel psychologists consult in human resources activities, from job definition to recruitment to employee appraisal. The *assessment center* approach (see the Personality modules), which includes simulated job tasks, may be used to evaluate potential and existing employees.

Appraising Performance

Performance appraisal serves organizational purposes: It helps decide who to keep on staff, how to appropriately reward and pay people, and how to better harness employee strengths, sometimes with job shifts or promotions. Performance appraisal also serves individual purposes: Feedback affirms workers' strengths and helps motivate needed improvements.

Performance appraisal methods include

- ***checklists*** on which supervisors simply check specific behaviors that describe the worker ("always attends to customers' needs"; "takes long breaks").
- ***graphic rating scales*** on which a supervisor checks, perhaps on a five-point scale, how often a worker is dependable, productive, and so forth.
- ***behavior rating scales*** on which a supervisor checks scaled behaviors that describe a worker's performance. If rating the extent to which a worker "follows procedures," the supervisor might mark the employee somewhere between "often takes

shortcuts" and "always follows established procedures" (Levy, 2003).

In some organizations, performance feedback comes not only from supervisors, but also from all organizational levels. If you join an organization that practices *360-degree feedback* (**FIGURE C.2**), you will rate yourself, your manager, and your other colleagues, and you will be rated by your manager, other colleagues, and customers (Green, 2002). The net result is often more open communication and more complete appraisal.

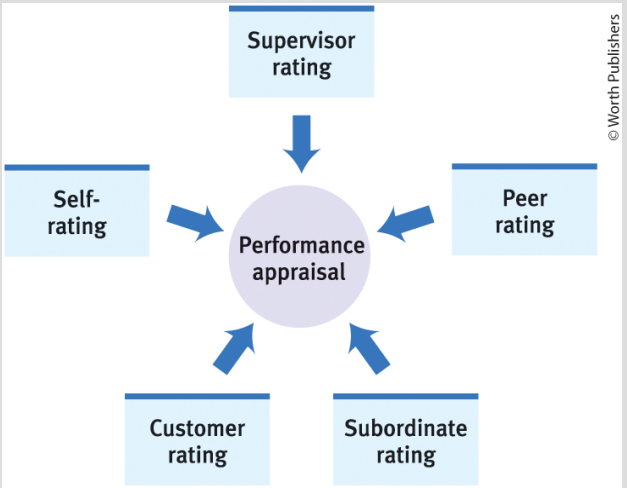

FIGURE C.2 360-degree feedback With multisource 360-degree feedback, our knowledge, skills, and behaviors are rated by ourselves and surrounding others. Professors, for example, may be rated by their department chairs, their students, and their colleagues. After receiving all these ratings, professors discuss the 360-degree feedback with their department chair.

Performance appraisal, like other social judgments, is vulnerable to bias (Murphy & Cleveland, 1995). *Halo errors* occur when one's overall evaluation of an employee, or of a personal trait such as their friendliness, biases ratings of their specific work-related behaviors, such as their reliability. *Leniency* and *severity errors* reflect evaluators' tendencies to be either too easy or too harsh on everyone. *Recency errors* occur when raters focus only on easily remembered recent behavior. By using multiple raters and developing objective, job-relevant performance measures, personnel psychologists seek to support their organizations while also helping employees perceive the appraisal process as fair.

Retrieval Practice

RP-2 A human resources director explains to you that "I don't bother with tests or references. It's all about the interview." Based on I/O psychology research, what concerns does this raise?

ANSWERS IN APPENDIX E

Organizational Psychology

Recruiting, hiring, training, and appraising capable and diverse workers matters, but so does employee motivation and morale. Organizational psychologists assist with efforts to motivate and engage employees, and they also explore effective leadership.

Satisfaction and Engagement at Work

LOQ C-4

Why are organizational psychologists interested in employee satisfaction and engagement?

I/O psychologists have found that satisfaction with work, and a desirable work-life balance, feed overall satisfaction with life (Bowling et al., 2010). Lower job stress (sometimes enabled by telecommuting) supports better health (Allen et al., 2015).

Satisfied employees also contribute to successful organizations. Positive moods at work enhance creativity, persistence, and helpfulness (Ford et al., 2011; Jeffrey et al., 2014; Shockley et al., 2012). Are engaged, happy workers also less often absent? Less likely to quit? Less prone to theft? More punctual? More productive? Statistical digests of prior research have found a modest positive correlation

between individual job satisfaction and performance (Judge et al., 2001; Ng et al., 2009). In one analysis, employee job satisfaction at 31 firms predicted those firms' profitability over the ensuing 4 years (Kessler et al., 2020).

Courtesy of New Lanark Trust

Doing well while doing good—"the great experiment" At the end of the 1700s, the New Lanark, Scotland, cotton mill had more than 1000 workers. Many were children drawn from Glasgow's poorhouses. They worked 13-hour days and lived in grim conditions.

On a visit to Glasgow, Welsh-born Robert Owen—an idealistic young cotton-mill manager—met and married the mill owner's daughter. Owen and some partners purchased the

mill and on the first day of the 1800s began what he called "the most important experiment for the happiness of the human race that had yet been instituted at any time in any part of the world" (Owen, 1814). The exploitation of child and adult labor was, he observed, producing unhappy and inefficient workers. Owen showed *transformational leadership* (discussed later in this appendix) when he undertook numerous innovations: a nursery for preschool children, education for older children (with encouragement rather than corporal punishment), Sundays off, health care, paid sick days, unemployment pay for days when the mill could not operate, and a company store selling goods at reduced prices. He also innovated a goals- and worker-assessment program that included detailed records of daily productivity and costs but with "no beating, no abusive language."

The ensuing commercial success fueled a humanitarian reform movement. By 1816, with decades of profitability still ahead, Owen believed he had demonstrated "that society may be formed so as to exist without crime, without poverty, with health greatly improved, with little if any misery, and with intelligence and happiness increased a hundredfold." Although his utopian vision has not been fulfilled, Owen's great experiment laid the groundwork for employment practices that have today become accepted in much of the world.

Some organizations seem to have a knack for cultivating more engaged and productive employees. In the United States, *Fortune*'s "100 Best Companies to Work For" have also produced markedly higher-than-average returns for their investors (Yoshimoto & Frauenheim, 2018). And consider a huge study of more than 198,000 employees in nearly 8000 business units of 36 large companies (including some 1100 bank branches, 1200 stores, and 4200 teams or departments). James Harter, Frank Schmidt, and Theodore Hayes (2002) explored correlations between various measures of organizational success and *employee engagement*—the extent of workers' involvement, enthusiasm, and identification with their organizations (**TABLE C.2**). They found that engaged workers (compared with not-engaged workers who are just putting in their

time) knew what was expected of them, had what they needed to do their work, felt fulfilled in their work, had regular opportunities to do what they do best, perceived that they were part of something significant, and had opportunities to learn and develop. They also found that business units with engaged employees had more loyal customers, lower turnover rates, higher productivity, and greater profits.

TABLE C.2 Three Types of Employees

- ***Engaged:*** Working with commitment and energy, and feeling connected to their company or organization.
- ***Not engaged:*** Putting in the time but investing little passion or energy in their work.
- ***Actively disengaged:*** Unhappy workers undermining what their colleagues accomplish.

Information from Gallup via Crabtree, 2005.

© 2023 MLive Media Group. All rights reserved. Used with permission.

An engaged employee Mohamed Mamow, left, was joined by his employer in saying the Pledge of Allegiance as he became a U.S. citizen. Mamow and his wife met in a Somali

> refugee camp. Since then, he has supported his family by working as a machine operator at a Michigan packaging company. Mindful of his responsibility—"I don't like to lose my job. I have a responsibility for my children and my family"—he would arrive for work a half hour early and tend to every detail on his shift. "He is an extremely hard-working employee," noted his employer, and "a reminder to all of us that we are really blessed" (Roelofs, 2010).

What percentage of employees are engaged? One massive study of 6.4 million people in 159 countries showed that only about 15 percent of workers reported being engaged (Gallup, 2017, 2020). Engagement is highest among people who have knowledge-based jobs, flexible hours, and freedom to work remotely. More organizations now offer such benefits in the hope of increasing employee engagement (Eisenberger et al., 2019).

But what causal arrows explain this correlation between business success and employee morale and engagement? Does success boost morale, or does high morale boost success? A longitudinal study of 142,000 workers found that, over time, employee attitudes predicted *future* business success (more than the other way around) (Harter et al., 2010). Many other studies confirm that happy workers tend to be good workers (Kleine et al., 2019; Walsh et al., 2018). A longitudinal study of 102 companies showed that employee engagement predicted future company success (Schneider et al., 2018). It pays to have engaged employees.

Task significance People find their work meaningful and engaging when it has *task significance*—when they view their work as benefiting others (Allan, 2017).

Effective Leadership

LOQ C-5

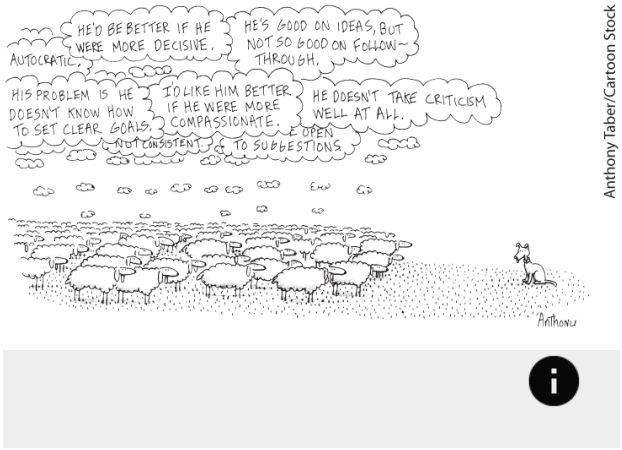
How can leaders be most effective?

Engaged employees don't just happen. Most have effective **leaders**—people who motivate and enable their group's success, and who engage their employees' interests and loyalty (Royal, 2019). Great managers support employees' well-being, articulate goals clearly, and lead in ways that suit the situation and consider the cultural context.

Setting Specific, Challenging Goals

Measurable objectives, such as "finish gathering the history paper information by Friday," focus our attention and stimulate us to persist and to be creative. Goals motivate achievement, especially when combined with progress reports (Harkin et al., 2016). Action plans

increase the odds of on-time completion when they (1) break large goals into smaller steps (subgoals), (2) specify *implementation intentions* (when, where, and how to achieve those steps), and (3) engage accountability (progress checks) (Fishbach et al., 2006; Gollwitzer & Sheeran, 2006). We best sustain our mood and motivation through a task's ups and downs when we focus on immediate goals (such as daily study) rather than distant goals (such as a course grade). Better to have our nose to the grindstone than our eye on the ultimate prize (Houser-Marko & Sheldon, 2008).



Thus, before beginning each new edition of this book, our author-editor team *manages by objectives*—we agree on target dates for completion of each module draft. Each week, we monitor our progress and make necessary adjustments. If we focus on achieving each of these short-term goals, then the prize—an on-time book—takes care of itself. So, to motivate high productivity, effective leaders work with people to define explicit goals, subgoals, and implementation plans, and then provide feedback on progress. Such goals are SMART—*s*pecific, *m*easurable, *a*ctionable, *r*ealistic, and *t*ime-bound (SIOP, 2018).

"Good leaders don't ask more than their constituents can give, but they often ask—and get—more than their constituents intended to give or thought it was possible to give." — John W. Gardner, *Excellence,* 1984

Choosing an Appropriate Leadership Style

Effective leaders of laboratory groups, work teams, and large corporations often exude *charisma* (Goethals & Allison, 2014; Tskhay et al., 2018). Charismatic people inspire others' loyalty and focus their enthusiasm (Grabo & van Vugt, 2016).

Charisma can bolster leadership, especially when combined with practical managerial skills (Vergauwe et al., 2018). What other qualities help? Leadership styles vary, depending on both the qualities of the leader and the demands of the situation (Badura et al., 2019). In some situations (think of a commander leading troops into battle), a *directive* style may be needed (Fiedler, 1981). In other situations—developing a comedy show, for example—a leader might get better results using a *democratic* style that welcomes team member creativity.

Leaders differ in the personal qualities they bring to the job. Some excel at **task leadership**. To keep the group centered on its mission,

task leaders typically use a directive style, which can work well if the leader gives good directions (Fiedler, 1987).

Other managers excel at **social leadership**. They explain decisions, help group members solve conflicts, and build teams that work well together (Bisbey et al., 2019; Pfaff et al., 2013). Social leaders, many of whom are women, often have a democratic style. They share authority and welcome team members' opinions. Social leadership and team-building increases morale and productivity (Shuffler et al., 2011, 2013). We usually feel more satisfied and motivated, and perform better, when we can participate in decision making (Cawley et al., 1998; Pereira & Osburn, 2007). Moreover, when members are sensitive to one another and participate equally, groups solve problems with greater "collective intelligence" (Woolley et al., 2010).

Luiz Rampelotto/NurPhoto/Getty Images

Social leadership Former Liberian president Ellen Johnson Sirleaf was Africa's first female elected head of state. After earlier being arrested for her opposition to government corruption, her charismatic leadership and achievements led to her receiving the 2011 Nobel Peace Prize for her "non-violent

> struggle for the safety of women and for women's rights to full participation in peace-building work."

In one study of 50 Dutch companies, the firms with the highest morale had chief executives who most inspired their colleagues "to transcend their own self-interests for the sake of the collective" (de Hoogh et al., 2004). *Transformational leadership* of this kind motivates others to identify with and fully commit themselves to the group's mission. Transformational leaders, many of whom are natural extraverts, articulate high standards, inspire people to share their vision, and offer personal attention (Bono & Judge, 2004). The frequent result is more engaged, trusting, and effective workers (Turner et al., 2002). Women more than men tend to exhibit transformational leadership qualities (G. Wang et al., 2018).

Studies in India, Taiwan, and Iran suggest that effective managers—whether in coal mines, banks, or government offices—often exhibit a high degree of *both* task and social leadership (Smith & Tayeb, 1989). As achievement-minded people, effective managers care about how well work is done, yet they are sensitive to their subordinates' needs. Workers in family-friendly organizations that offer flexible hours report feeling greater job satisfaction and loyalty to their employers (Butts et al., 2013; Roehling et al., 2001). Social virtues work.

Positive Reinforcement

Effective leadership often builds on a basic principle of *operant conditioning:* To teach a behavior, catch a person doing something right and reinforce it. It sounds simple, but many managers are like parents who, when a child brings home a near-perfect school report card, focus on the one low grade in a troublesome class and ignore the rest. “Sixty-five percent of Americans received NO praise or recognition in the workplace last year,” reported the Gallup organization (2004).

Scott Eklund/AP Photo

The power of positive coaching Football coach Pete Carroll, who led the University of Southern California to two national championships and the Seattle Seahawks to a Super Bowl championship, combined positive enthusiasm and fun workouts with “a commitment to a nurturing environment that allows people to be themselves while still being accountable to the team” (Trotter, 2014). “It shows you can win with positivity,” noted former Seahawks defensive star Richard Sherman. “It’s literally all positive

reinforcement," said teammate Jimmy Graham (Belson, 2015).

Fulfilling the Need to Belong

A work environment that satisfies employees' need to belong is energizing. Employees who enjoy high-quality colleague relationships engage in their work with more vigor (Carmeli et al., 2009). Gallup researchers have asked more than 15 million employees worldwide if they have a "best friend at work." The 30 percent who do "are *seven times* as likely to be engaged in their jobs" as those who don't, report Tom Rath and James Harter (2010). And, as we noted earlier, positive, engaged employees are a mark of thriving organizations.

"Department hug in five."

Participative Management

Employee participation in decision making is common in Sweden, Japan, the United States, and elsewhere (Cawley et al., 1998;

Sundstrom et al., 1990). Workers given a chance to voice their opinion and be part of the decision-making process have responded more positively to the final decision (van den Bos & Spruijt, 2002). They also feel more empowered, and are likely, therefore, to be more creative and committed (Hennessey & Amabile, 2010; Seibert et al., 2011).

The ultimate in employee participation is the employee-owned company. Approximately 6500 such companies exist in the United States—including Publix Supermarkets with its nearly 225,000 employees (Lapp, 2019; NCEO, 2022; Publix, 2022; Quinton, 2020). One such company in my [DM's] town is the Fleetwood Group, a thriving 165-employee manufacturer of educational furniture and wireless communication devices. Every employee owns part of the company, and as a group they own 100 percent. The more years employees work, the more they own, yet no one owns more than 5 percent. Like every corporate president, Fleetwood's president works for his stockholders—who also just happen to be his employees.

As a company that endorses faith-inspired "respect and care for each team member- owner," Fleetwood is free to place people above profits. Thus, when orders lagged during a recession, the employee-owners decided that job security meant more to them than profits. So the company paid otherwise idle workers to do community service, such as answering phones at nonprofit agencies and building Habitat for Humanity houses. Employee ownership attracts and retains talented people, which for Fleetwood has meant company success.

Cultural Influences on Leadership Styles

LOQ C-6

What cultural influences need to be considered when choosing an effective leadership style?

I/O psychology sprang from North American roots. So, how well do its leadership principles apply to cultures worldwide?

One worldwide investigation, Project GLOBE (Global Leadership and Organizational Behavior Effectiveness), has studied cultural variations in leadership expectations (House et al., 2001). Some cultures, for example, encourage collective sharing of resources and rewards; others are more individualist. Some cultures minimize and others accentuate traditional gender roles. Some cultures prioritize being friendly, caring, and kind, and others encourage a "me-first" attitude. The program's first research phase studied 17,300 leaders of 950 organizations in 61 countries (Brodbeck et al., 2008; Dorfman et al., 2012). One finding: Leaders who fulfill expectations, such as by being directive in some cultures or participative in others, tend to be successful. Cultures shape leadership and what makes for leadership success.

Nevertheless, some leader behaviors are universally effective. From its massive study of nearly 50,000 business units in 45 countries, Gallup observed that thriving companies tend to focus on identifying

and enhancing employee *strengths* (rather than punishing their deficiencies). Doing so predicts increased employee engagement, customer satisfaction, and profitability (Rigoni & Asplund, 2016a,b). *Strengths-based* leadership pays dividends, supporting happier, more creative, more productive employees in workplaces with less absenteeism and turnover (Amabile & Kramer, 2011; De Neve et al., 2013).

Moreover, the same principles affect student satisfaction, retention, and future success (Larkin et al., 2013; Ray & Kafka, 2014). Students who feel supported by caring friends and mentors tend to persist and ultimately succeed during school and after graduation.

***

We have considered *personnel psychology* (the I/O psychology subfield that focuses on training job seekers, and assisting with employee selection, placement, appraisal, and development). And we have considered *organizational psychology* (the I/O psychology subfield that focuses on worker satisfaction and productivity, and on organizational change). Finally, we turn to *human factors psychology,* which explores the human-machine interface.

Ask Yourself

ANSWERS IN APPENDIX E

Human Factors Psychology

LOQ C-7

How do human factors psychologists work to create user-friendly machines and work settings?

Designs sometimes neglect the human factor. Cognitive scientist Donald Norman (2001) bemoaned the complexity of assembling his new HDTV, related components, and seven remotes into a usable home theater system: "I was VP of Advanced Technology at Apple. I can program dozens of computers in dozens of languages. I understand television, really, I do.... It doesn't matter: I am overwhelmed." Norman hosts a website (jnd.org) that illustrates good designs that fit people (**FIGURE C.3**).

Top: Ride On Carry On; bottom: OXO Good Grips

FIGURE C.3 Designing products that fit people Human factors expert Donald Norman offers these and other examples of effectively designed products. The Ride On

Carry On foldable chair attachment, “designed by a flight attendant mom,” enables a small suitcase to double as a stroller. The OXO measuring cup allows the user to see the quantity from above.

Human factors psychologists work with designers and engineers to tailor appliances, machines, and work settings to our natural perceptions and inclinations. Bank ATM machines are internally more complex than remote controls ever were, yet thanks to human factors engineering, ATMs are easier to operate. Digital recorders have solved the TV recording problem with a simple select-and-click menu system (“record that one”). Handheld and wearable technologies are increasingly making use of *haptic* (touch-based) feedback—opening a phone with a thumbprint, sharing your heartbeat via a smartwatch, or having GPS directional instructions (“turn left” arrow) “drawn” on your skin with other wrist-worn devices.

Human factors psychologists also help design efficient environments. An ideal kitchen layout, researchers have found, puts needed items close to their usage point and near eye level. It locates work areas to enable doing tasks in order, such as placing the refrigerator, stove, and sink in a triangle. It creates counters that enable hands to work at or slightly below elbow height (Boehm-Davis, 2005).

Understanding human factors can help prevent accidents. By studying the human factor in driving accidents, psychologists seek to devise

ways to reduce the distractions, fatigue, and inattention that contribute to 1.25 million annual worldwide traffic fatalities (WHO, 2016). At least two-thirds of commercial air accidents have been caused by human error (Shappell et al., 2007). After beginning commercial flights in the 1960s, the Boeing 727 was involved in several landing accidents caused by pilot error. Psychologist Conrad Kraft (1978) noted a common context for these accidents: All took place at night, and all involved landing short of the runway after crossing a dark stretch of water or unilluminated ground. Kraft reasoned that, on rising terrain, city lights beyond the runway would project a larger retinal image, making the ground seem farther away than it was. By re-creating these conditions in flight simulations, Kraft discovered that pilots were deceived into thinking they were flying higher than their actual altitudes (FIGURE C.4). Aided by Kraft's finding, airlines began requiring the co-pilot to monitor the altimeter—calling out altitudes during the descent—and the accidents diminished.

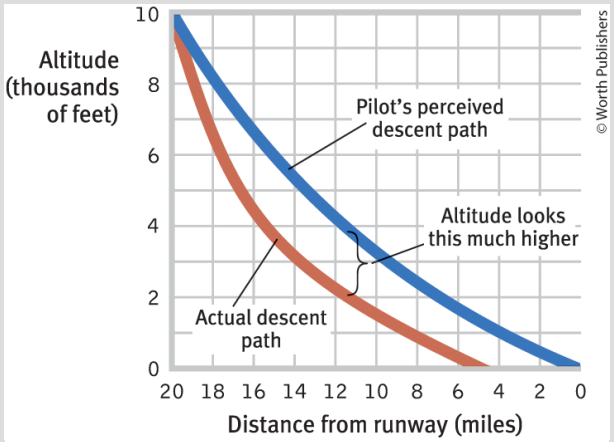

FIGURE C.4 The human factor in accidents
Lacking distance cues when approaching a runway from over a dark surface, pilots

simulating a night landing tended to fly too low. (Data from Kraft, 1978.)

Human factors psychologists can also help us to function in other settings. Consider the available *assistive listening* technologies in various theaters, auditoriums, and places of worship. One technology, commonly available in the United States, requires a headset attached to a pocket-sized receiver. The well-meaning people who provide these systems correctly understand that the technology puts sound directly into the user's ears. Alas, few people with hearing loss elect the hassle and embarrassment of locating, requesting, wearing, and returning a conspicuous headset. Most such units therefore sit in closets. Britain, the Scandinavian countries, Australia, and now many parts of the United States have instead installed *loop systems* (see HearingLoop.org) that broadcast customized sound directly through a person's own hearing aid. When suitably equipped, a hearing aid can be transformed by a discreet touch of a switch into a customized in-the-ear speaker. When offered convenient, inconspicuous, personalized sound, many more people elect to use assistive listening.

Designs that enable safe, easy, and effective interactions between people and technology often seem obvious after the fact. Why, then, aren't they more common? Technology developers, like all of us, sometimes mistakenly assume that others share their expertise—that what's clear to them will similarly be clear to others (Camerer et al., 1989; Nickerson, 1999). When people rap their knuckles on a table to

convey a familiar tune (try this with a friend), they often expect their listener to recognize it. But for the listener, this is a near-impossible task (Newton, 1991). When you know a thing, it's hard to mentally simulate what it's like not to know, and that is called the *curse of knowledge.* As psychologist Steven Pinker (2014) has noted, "The better you know something, the less you remember about how hard it was to learn."

The point to remember: Everyone benefits when designers and engineers tailor machines, technologies, and environments to fit human abilities and behaviors, when they user-test their work before production and distribution, and when they remain mindful of the curse of knowledge.

Steven Day/AP Photo

The human factor in safe landings Advanced cockpit design and rehearsed emergency procedures aided pilot Chesley "Sully" Sullenberger, a U.S. Air Force Academy graduate who earned a master's degree in industrial psychology. In 2009, Sullenberger's instantaneous decisions safely guided his disabled airplane onto New York City's Hudson River, where all 155 of the passengers and crew were safely evacuated.

Ask Yourself

1. People whose work fully engages their skills often experience _____, a focused state of consciousness, with diminished awareness of themselves and of time.

2. _____ psychologists assist with job seeking, and the recruitment, selection, placement, training, appraisal, and development of employees; _____ _____ psychologists focus on how people and machines interact, and on optimizing devices and work environments.

3. A personnel psychologist scripted a set of questions to ask all applicants for a job opening. She then trained the firm's interviewers to ask only those questions, to take notes, and to rate applicants' responses. This technique is known as a(n)
   a. structured interview.
   b. unstructured interview.
   c. performance appraisal checklist.
   d. behavior rating scale.

4. In your job, you rate your own performance, your manager's, and your peers'. Your manager, your peers, and your customers in turn rate your performance. Your organization is using a form of performance appraisal called
   a. the assessment center approach.
   b. graphic feedback.

c. structured interviews.
d. 360-degree feedback.

5. What are SMART goals, and why are they effective?

6. Research indicates that women are often social leaders. They are also more likely than men to have a _____ leadership style.

7. Effective managers often exhibit
   a. only task leadership.
   b. only social leadership.
   c. both task and social leadership, depending on the situation and the person.
   d. task leadership for building teams and social leadership for setting standards.

8. Human factors psychologists focus primarily on
   a. training and developing employees.
   b. appraising employee performance.
   c. maximizing worker satisfaction.
   d. improving the design of machines and environments.

Complete Module Reviews

Chapter 1 Thinking Critically With Psychological Science (Modules 1–3)

Module 1: The History and Scope of Psychology

1-1 How is psychology a science?

Psychology's findings, based on an empirical approach, are the result of careful observation and testing. Sifting reality from fantasy requires a scientific attitude.

1-2 What are the three key elements of the scientific attitude, and how do they support scientific inquiry?

The scientific attitude equips us to be curious, skeptical, and humble in scrutinizing competing ideas or our own observations. Curiosity triggers new ideas, skepticism encourages attention to the facts, and humility helps us both discard predictions that can't be verified by research and be open to surprises. Together, these three key elements make modern science possible.

1-3 How does critical thinking feed a scientific attitude, and smarter thinking for everyday life?

Critical thinking puts ideas to the test by examining assumptions, appraising the source, discerning hidden biases, evaluating evidence, and assessing conclusions.

1-4 What were some important milestones in psychology's early history?

Wilhelm Wundt established the first psychological laboratory in 1879 in Germany. Two early schools of thought in psychology were *structuralism* and *functionalism*. Mary Whiton Calkins and Margaret Floy Washburn were two of the first women in the field.

1-5 How did behaviorism, Freudian psychology, and humanistic psychology further the development of psychological science?

Early researchers defined *psychology* as "the science of mental life." In the 1920s, under the influence of John B. Watson and the behaviorists, the field's focus changed to the "scientific study of observable behavior." *Behaviorism* became one of psychology's two major forces well into the 1960s. However, the second major force of Freudian (psychoanalytic) psychology, along with the influence of *humanistic psychology*, revived interest in the study of mental processes.

1-6 How has contemporary psychology focused on cognition, on biology and experience, on culture and gender, and on human flourishing?

The *cognitive revolution* in the 1960s led psychology back to its early interest in the mind, and to its current definition as the science of behavior and mental processes. The field of *cognitive neuroscience* now examines the brain activity underlying mental activity. Our growing understanding of biology and experience has fed psychology's most enduring debate. The *nature–nurture issue* centers on the relative contributions of genes and experience, and their interaction in specific environments. Charles Darwin's view that *natural selection* shapes behaviors as well as bodies led to *evolutionary psychology*'s study of our similarities because of our common biology and evolutionary history, and *behavior genetics*' focus on the relative power and limits of genetic and environmental influences on behavior. Cross-cultural and gender studies have diversified psychology's assumptions while also reminding us of our similarities. Attitudes and behaviors may vary somewhat by gender or across *cultures,* but because of our shared human kinship, the underlying processes and principles are more similar than different. Psychology's traditional focus on understanding and treating troubles has expanded with *positive psychology*'s call for more research on human flourishing and its attempt to discover and promote traits that help people to thrive.

1-7 How do psychologists use the biopsychosocial approach, and how can it help us understand our diverse world?

The *biopsychosocial approach* integrates information from three differing but complementary *levels of analysis*: biological,

psychological, and social-cultural. This approach offers a more complete understanding than could usually be reached by relying on only one of psychology's current theoretical perspectives (neuroscience, evolutionary, behavior genetics, psychodynamic, behavioral, cognitive, and social-cultural). The biopsychosocial approach can help us understand our diverse world: We share a biologically rooted nature, but many psychological and social-cultural influences fine-tune our assumptions, values, and behavior.

1-8 What are psychology's main subfields?

Within the science of psychology, researchers may conduct *basic research* to increase the field's knowledge base (often in biological, developmental, cognitive, personality, and social psychology) or *applied research* to solve practical problems (in industrial-organizational psychology and other areas). Those who engage in psychology as a helping profession may assist people as *counseling psychologists*, helping people with challenges and crises (including academic, vocational, and relationship issues) and to improve their personal and social functioning, or as *clinical psychologists*, assessing and treating people with mental, emotional, and behavior disorders. *Psychiatrists* also assess and treat people with disorders, but as medical doctors, they may prescribe drugs in addition to psychotherapy. *Community psychologists* work to create healthy social and physical environments (in schools and neighborhoods, for example).

1-9 How can psychological principles help you learn, remember, and thrive?

The *testing effect* shows that learning and memory are enhanced by actively retrieving, rather than simply rereading, previously studied material. The *SQ3R* study method—survey, question, read, retrieve, and review—applies principles derived from memory research and can help you learn and remember material. Four additional tips are (1) distribute your study time; (2) learn to think critically; (3) process class information actively; and (4) overlearn. Psychological research has shown that people who live happy, thriving lives manage their time to get a full night's sleep; make space for exercise; set long-term goals, with daily aims; have a growth mindset; and prioritize relationships.

Module 2: Research Strategies: How Psychologists Ask and Answer Questions

2-1 How does our everyday thinking sometimes lead us to a wrong conclusion?

Our everyday thinking can lead us astray because of three phenomena. *Hindsight bias* (the "I-knew-it-all-along phenomenon") is the tendency to believe, after learning an outcome, that we would have foreseen it. Overconfidence is often the result of our readiness to be more confident than correct. These tendencies, along with our

eagerness to perceive patterns in random events, lead us to overestimate the weight of commonsense thinking. Scientific inquiry can help us overcome such biases and shortcomings.

2-2 Why are we so vulnerable to believing untruths?

In our modern "post-truth" culture, our emotions, beliefs, and group affiliations may color our judgments, prevent our acknowledgement of objective facts, and prompt us to accept only the information that confirms our views. Misinformation may spread as a result of repetition and memorable examples, contributing to the post-truth culture. Critical evaluation of information and a scientific mindset can help to combat our biases and distorted thinking.

2-3 How do theories advance psychological science?

Psychological *theories* apply an integrated set of principles to organize observations and to generate *hypotheses*. By testing their hypotheses, researchers can confirm, reject, or revise their theories. To enable other researchers to *replicate* the studies, researchers report them using precise *operational definitions* of their procedures and concepts. If others achieve similar results, confidence in the conclusion will be greater. More and more psychologists use *preregistration* to publicly communicate their planned study design, hypotheses, data collection, and analyses, which promotes openness and transparency. By combining the results of many studies, *meta-analysis* helps increase researchers' confidence in their results by avoiding the problem of small sample sizes.

2-4 How do psychologists use case studies, naturalistic observations, and surveys to observe and describe behavior, and why is random sampling important?

Descriptive methods, which include *case studies* (in-depth analyses of individuals or groups), *naturalistic observations* (recording many individuals' natural behavior), and *surveys* (asking people questions), show us what can happen, and they may offer ideas for further study. The best basis for generalizing about a *population* is a representative sample; in a *random sample*, every person in the entire population being studied has an equal chance of participating. Descriptive methods describe but do not *explain* behavior; they cannot show cause and effect because researchers cannot control variables.

2-5 What does it mean when we say two things are correlated, and what are positive and negative correlations?

Correlation is the degree to which two variables are related, and how well one predicts the other. In a positive correlation, two variables increase or decrease together; in a negative correlation, one variable increases as the other decreases. The strength and direction of their relationship is expressed as a *correlation coefficient*, which ranges from +1.00 (a perfect positive correlation) through 0 (no correlation) to −1.00 (a perfect negative correlation).

2-6 What are *illusory correlations*, and what is *regression toward the mean?*

Illusory correlations are random events that we notice and falsely assume are related.

2-7 Why do correlations enable prediction but not cause-effect explanation?

Correlations enable prediction because they show how two factors are related—either positively or negatively. A correlation can indicate the possibility of a cause-effect relationship, but it does not prove the direction of the influence, or whether an underlying third factor may explain the correlation.

2-8 What are the characteristics of experimentation that make it possible to isolate cause and effect?

To discover cause-effect relationships, psychologists conduct *experiments*, manipulating one or more variables of interest and controlling other variables. Using *random assignment*, they can minimize confounding variables, such as preexisting differences between the *experimental group* (exposed to the treatment) and the *control group* (not given the treatment). The *independent variable* is the factor the experimenter manipulates to study its effect; the *dependent variable* is the factor the experimenter measures to discover any changes occurring in response to the manipulation of

the independent variable. Studies may use a *double-blind procedure* to avoid the *placebo effect* and researcher bias.

2-9 How would you know which research design to use?

Psychological scientists design studies and choose research methods that will best provide meaningful results. Researchers generate testable questions, and then carefully consider the best design to use in studying those questions (experimental, correlational, case study, naturalistic observation, twin study, longitudinal, or cross-sectional). Next, psychologists measure the variables they are studying, and finally they interpret their results, keeping possible confounding variables in mind. (The online *How Would You Know?* research activities allow you to play the role of the researcher, making choices about the best ways to test interesting questions.)

2-10 How can simplified laboratory experiments help us understand general principles of behavior?

Researchers intentionally create a controlled, artificial environment in the laboratory to test general theoretical principles. It is the general principles—not the specific findings—that help explain everyday behaviors.

2-11 Why do psychologists study animals, and what ethical research guidelines safeguard human and animal welfare? How do psychologists' values influence what they study and how they apply their results?

Some psychologists are primarily interested in animal behavior; others want to better understand the physiological and psychological processes shared by humans and other species. Government agencies have established standards for animal care and housing. Professional associations and funding agencies also have guidelines for protecting animals' well-being. The ethics codes of the American Psychological Association (APA) and the British Psychological Society (BPS) outline standards for safeguarding human participants' well-being, including obtaining their *informed consent* and *debriefing* them later. Universities and research organizations have Institutional Review Boards to screen research proposals and ensure participants' well-being. Scientific scrutiny and replication help to guard against the fabrication of data, which has the potential to cause great harm. Psychologists' values influence their choice of research topics, their theories and observations, and their labels for behavior. Applications of psychology's principles have been used mainly in the service of humanity

Module 3: Statistical Reasoning in Everyday Life

3-1 Why does statistical literacy matter?

Statistical literacy involves not only the ability to understand numbers and basic math, but also the ability to think about what numbers mean in context. Improving your statistical literacy will

give you a more accurate understanding of the world and the people around you, and a clearer sense of the risks that affect your life.

3-2 How do we describe data using three measures of central tendency?

Researchers use descriptive statistics to measure and describe characteristics of groups under study. A measure of central tendency is a single score that represents a whole set of scores. Three such measures that we use to describe data are the *mode* (the most frequently occurring score), the *mean* (the arithmetic average), and the *median* (the middle score in a group of data).

3-3 What is the relative usefulness of the two measures of variation?

Measures of central tendency neatly summarize data; measures of variation tell us how diverse data are. Two measures of variation are the *range* (which describes the gap between the highest and lowest scores) and the *standard deviation* (which states how much scores vary around the mean, or average, score). Scores often form a *normal* (or bell-shaped) *curve*.

3-4 How do we know whether an observed difference can be generalized to other populations?

Researchers use inferential statistics (which include ways of determining the reliability and significance of an observed

difference between the results for different groups) to determine if results can be generalized to a larger population. Reliable differences are based on samples that are representative of the larger population being studied; that demonstrate low variability, on average; that consist of many cases; and that comprise multiple studies (using *meta-analysis*). The effect size—the size of the difference between groups—helps determine *statistical significance*: When the sample averages are reliable and the difference between them is large, we can reject the null hypothesis of no existing differences. Many psychological tests provide *p-values*, which indicate the probability of the null hypothesis being true given the sample data.

Chapter 2 The Biology of Mind (Modules 4–7)

Module 4: Neural and Hormonal Systems

4-1 Why are psychologists concerned with human biology?

Psychologists working from a *biological* perspective study the links between biological processes and psychological processes. We are biopsychosocial systems, in which biological, psychological, and social-cultural factors interact to influence behavior.

4-2 How do biology and experience together enable neuroplasticity?

Neuroplasticity enables our brain to build new neural pathways as we adjust to new experiences; so, our brain is sculpted by both genes and life. While neuroplasticity is lifelong, it is greatest early in life. With practice, our brain develops unique patterns that reflect our life experiences.

4-3 What are *neurons,* and how do they transmit information?

Neurons are the elementary components of the nervous system, the body's speedy electrochemical information system. A neuron (a *cell*

body and its branching fibers) receives signals through its often bushy, branching *dendrites* and sends signals through its *axons.* Some axons are encased in a *myelin sheath,* which enables faster transmission. *Glial cells* support, nourish, and protect neurons and also play a role in learning, thinking, and memory. If the combined signals received by a neuron exceed a minimum *threshold,* the neuron fires, transmitting an electrical impulse (the *action potential*) down its axon by means of a chemistry-to-electricity process. Neurons need a short rest called the *refractory period,* after which they can fire again. The neuron's reaction is an *all-or-none response.*

4-4 How do nerve cells communicate with other nerve cells?

When action potentials reach the end of an axon (the button-like axon terminals), they stimulate the release of *neurotransmitters.* These chemical messengers carry a message from the sending neuron across a *synapse* to receptor sites on a receiving neuron. The sending neuron, in a process called *reuptake,* then normally reabsorbs the excess neurotransmitter molecules in the synaptic gap. If incoming signals are strong enough, the receiving neuron generates its own action potential and relays the message to other cells.

4-5 How do neurotransmitters influence behavior, and how do drugs and other chemicals affect neurotransmission?

Neurotransmitters travel designated pathways in the brain and may influence specific behaviors and emotions. Acetylcholine (ACh) enables muscle action, learning, and memory. *Endorphins* are natural opioids released in response to pain and exercise. Drugs and other chemicals affect brain chemistry at synapses. *Agonists* increase a neurotransmitter's action, and may do so in various ways. *Antagonists* decrease a neurotransmitter's action by blocking production or release.

4-6 What are the functions of the nervous system's main divisions, and what are the three main types of neurons?

The *central nervous system (CNS)*—the brain and the spinal cord—is the *nervous system's* decision maker. The *peripheral nervous system (PNS)*, which connects the CNS to the rest of the body by means of *nerves*, gathers information and transmits CNS decisions to the rest of the body. The two main PNS divisions are the *somatic nervous system* (which enables voluntary control of the skeletal muscles) and the *autonomic nervous system* (which controls involuntary muscles and glands by means of its *sympathetic* and *parasympathetic* divisions). The three types of neurons cluster into working networks: (1) *Sensory (afferent) neurons* carry incoming information from the body's tissues and sensory receptors to the brain and spinal cord. (2) *Motor (efferent) neurons* carry outgoing information from the brain and spinal cord to the muscles and glands. (3) *Interneurons*

communicate within the brain and spinal cord and process information between the sensory inputs and motor outputs.

4-7 How does the endocrine system transmit information and interact with the nervous system?

The *endocrine system's* glands and fat tissue secrete *hormones* into the bloodstream; these hormones travel through the body and affect other tissues, including the brain. The endocrine system's master gland, the *pituitary*, influences hormone release by other glands, including the *adrenal glands.* In an intricate feedback system, the brain's hypothalamus influences the pituitary gland, which influences other glands, which release hormones, which in turn influence the brain.

Module 5: Tools of Discovery: Having Our Head Examined

5-1 How do neuroscientists study the brain's connections to behavior and mind?

Clinical observations and lesioning reveal the general effects of brain damage. Electrical, chemical, or magnetic stimulation can also reveal aspects of information processing in the brain. MRI scans show anatomy. EEG, MEG, PET, and fMRI (functional MRI) recordings reveal brain function.

Module 6: Brain Regions and Structures

6-1 What are the *hindbrain, midbrain,* and *forebrain?*

Vertebrate brains have three main divisions. The *hindbrain* contains brainstem structures that direct essential survival functions, such as breathing, sleeping, arousal, coordination, and balance. The *midbrain* connects the hindbrain with the forebrain; it controls some movement and transmits information that enables seeing and hearing. The *forebrain* manages complex cognitive activities, sensory and associative functions, and voluntary motor activities.

6-2 What structures make up the brainstem, and what are the functions of the brainstem, thalamus, reticular formation, and cerebellum?

The *brainstem* is responsible for automatic survival functions. It includes the *medulla* (which controls heartbeat and breathing), the pons (which helps coordinate movements and control sleep), and the *reticular formation* (which filters incoming stimuli, relays information to other brain areas, and affects arousal). The *thalamus*, sitting above the brainstem, acts as the brain's sensory control center. The *cerebellum*, attached to the rear of the brainstem, coordinates voluntary movement and balance and enables nonverbal learning and memory.

6-3 What are the limbic system's structures and functions?

The *limbic system* is linked to emotions, memory, and drives. Its neural centers include the *amygdala* (involved in behavioral and emotional responses, such as aggression and fear); the *hypothalamus* (directs various bodily maintenance functions, helps govern the endocrine system, and is linked to emotion and reward); and the *hippocampus* (helps process explicit, conscious memories). The hypothalamus controls the pituitary (the "master gland") by stimulating it to trigger the release of hormones.

6-4 What four lobes make up the cerebral cortex, and what are the functions of the motor cortex, somatosensory cortex, and association areas?

The *cerebral cortex* has two hemispheres, and each hemisphere has four lobes: *frontal, parietal, occipital*, and *temporal*. Each lobe performs many functions and interacts with other areas of the cortex. The *motor cortex*, at the rear of the frontal lobes, controls voluntary movements. The *somatosensory cortex*, at the front of the parietal lobes, registers and processes body touch and movement sensations. Body parts requiring precise control (in the motor cortex) or those that are especially sensitive (in the somatosensory cortex) occupy the greatest amount of space. Most of the brain's cortex—the major portion of each of the four lobes—is devoted to uncommitted *association areas*, which integrate information involved in higher mental functions such as learning, remembering,

thinking, and speaking. Our mental experiences arise from coordinated brain activity.

6-5 Is it true that 90 percent of our brain isn't really used?

The unresponsiveness of our association areas to electrical probing led to the false claim that we use only 10 percent of our brain. But these vast areas of the brain are responsible for interpreting, integrating, and acting on sensory information and linking it with stored memories. Evidence from brain damage shows that the neurons in association areas are busy with higher mental functions; a bullet would not land in an "unused" area.

Module 7: Damage Responses and Brain Hemispheres

7-1 To what extent can a damaged brain reorganize itself, and what is *neurogenesis?*

While brain and spinal cord neurons usually do not regenerate, some neural tissue can reorganize in response to damage. The damaged brain may demonstrate neuroplasticity, especially in young children, as new pathways are built and functions migrate to other brain regions. Reassignment of functions to different areas of the brain may also occur in blindness and deafness, or as a result of damage and disease. Some research suggests that the brain may

sometimes mend itself by forming new neurons, a process known as *neurogenesis.*

7-2 What do split brains reveal about the functions of our two brain hemispheres?

Split-brain research (experiments on people with a severed *corpus callosum*) has confirmed that in most people, the left hemisphere is the more verbal. The right hemisphere excels in visual perception and making inferences, and helps us modulate our speech and orchestrate our self-awareness. Studies of the intact brain in healthy people confirm that each hemisphere makes unique contributions to the integrated functioning of the whole brain.

Chapter 3 Consciousness and the Two-Track Mind (Modules 8–10)

Module 8: Basic Consciousness Concepts

8-1 What is the place of *consciousness* in psychology's history?

After initially claiming consciousness as their area of study in the nineteenth century, psychologists abandoned it in the first half of the twentieth century, turning instead to the study of observable behavior because they believed consciousness was too difficult to study scientifically. Since the 1960s, our awareness of ourselves and our environment—our *consciousness*—has reclaimed its place as an important area of research, such as in the interdisciplinary field of *cognitive neuroscience.*

8-2 How does *selective attention* direct our perceptions?

We *selectively attend* to, and process, a very limited portion of incoming information, blocking out much and often shifting the spotlight of our attention from one thing to another. Focused intently on one task, we often display *inattentional blindness* to other events, including *change blindness* to changes around us.

8-3 What is the *dual processing* being revealed by today's cognitive neuroscience?

Scientists studying the brain mechanisms underlying consciousness and cognition have discovered that the mind processes information on two separate tracks, one operating at a conscious level *(sequential processing)* and the other at an unconscious level *(parallel processing)*. Parallel processing takes care of the routine business, while sequential processing is best for solving new problems that require our attention. Together, this *dual processing*—conscious and unconscious—affects our perception, memory, attitudes, and other cognitions.

Module 9: Sleep and Dreams

9-1 What is *sleep?*

Sleep is the periodic, natural loss of normal consciousness—as distinct from unconsciousness resulting from a coma, general anesthesia, or hibernation.

9-2 How do our biological rhythms influence our daily functioning?

Our bodies have an internal biological clock, roughly synchronized with the 24-hour cycle of night and day. This *circadian rhythm* appears in our daily patterns of body temperature, arousal, sleeping,

and waking. Age and experience can alter these patterns, resetting our biological clock.

9-3 What is the biological rhythm of our sleeping and dreaming stages?

Younger adults cycle through four distinct sleep stages about every 90 minutes. (The sleep cycle repeats more frequently for older adults.) Leaving the *alpha waves* of the awake, relaxed stage, we descend into the irregular brain waves of N1 sleep, often with *hallucinations.* N2 sleep (in which we spend about half our sleep time) follows, lasting about 20 minutes, with its characteristic sleep spindles. We then enter N3 sleep, lasting about 30 minutes, with large, slow *delta waves.* About an hour after falling asleep, we ascend from our initial sleep dive and begin periods of *REM* (rapid eye movement or *R*) *sleep.* REM sleep, which includes most dreaming, is described as a paradoxical sleep stage because of internal arousal but external calm (near paralysis). During a normal night's sleep, N3 sleep shortens and REM and N2 sleep lengthen.

9-4 How do biology and environment interact in our sleep patterns?

Our biology—our circadian rhythm as well as our age and our body's production of melatonin (influenced by the brain's *suprachiasmatic nucleus*)—interacts with social, cultural, and economic influences and individual emotions and behaviors to determine our sleeping and waking patterns. Being bathed in (or deprived of) light disrupts

our 24-hour biological clock. Those who are chronically deprived of natural sunlight, such as night-shift workers, may experience desynchronization. Artificial light, including from light-emitting electronic devices, delays sleep and affects sleep quality.

9-5 What are sleep's functions?

Sleep may have played a protective role in human evolution by keeping people safe during potentially dangerous periods. Sleep also helps restore the immune system and repair damaged neurons. Sleep consolidates our memories by replaying recent learning and strengthening neural connections. Sleep promotes creative problem solving the next day. During slow-wave sleep, the pituitary gland secretes a growth hormone necessary for muscle development. As a result of these benefits, a regular full night's sleep can greatly enhance athletic performance.

9-6 How does sleep loss affect us, and what are the major sleep disorders?

Sleep deprivation causes fatigue and irritability, and it impairs concentration and memory consolidation. It can also lead to depression, obesity, joint inflammation, a suppressed immune system, and slowed performance (with greater vulnerability to accidents). Sleep disorders include *insomnia* (recurring problems in falling or staying asleep); *narcolepsy* (sudden uncontrollable sleepiness, sometimes lapsing directly into REM sleep); *sleep apnea* (the repeated stopping of breathing while asleep; associated with

obesity, especially in men); *REM sleep behavior disorder* (acting out dreams by moving or speaking while asleep); *night terrors* (high arousal and the appearance of being terrified; N3 disorder found mainly in children); sleepwalking; and sleeptalking.

9-7 What do we dream, and what functions have theorists proposed for dreams?

We usually *dream* of ordinary events and everyday experiences, most involving some anxiety or misfortune. Fewer than 10 percent of dreams among men (and fewer still among women) have any sexual content. Most dreams occur during REM sleep. There are five major views of the function of dreams. (1) Freud's wish fulfillment: Dreams provide a psychic "safety valve," with *manifest content* (story line) acting as a censored version of *latent content* (underlying meaning that gratifies our unconscious wishes). (2) Information processing: Dreams help us sort out the day's events and consolidate them in memory. (3) Neurocognitive function: REM sleep preserves memory and processes emotional information. (4) Activation synthesis: The brain attempts to make sense of neural static by weaving it into a story line. (5) Cognitive development: Dreams reflect the dreamers' level of development—their knowledge and understanding. Most sleep theorists agree that REM sleep and its associated dreams serve an important function, as shown by the *REM rebound* that occurs following REM deprivation in humans and other species.

Module 10: Drugs And Consciousness

10-1 What are *substance use disorders?*

Those with a *substance use disorder* experience continued substance craving and use despite significant life disruption and/or physical risk. *Psychoactive drugs* alter perceptions and moods. A substance/medication-induced disorder occurs when drug use causes changes that resemble a psychological disorder.

10-2 What roles do tolerance and addiction play in substance use disorders, and how has the concept of *addiction* changed?

Psychoactive drugs may produce *tolerance*—requiring larger doses to achieve the desired effect, a result of neuroadaptation—and *withdrawal*—the discomfort and distress that follow discontinuing an addictive drug or behavior. Addiction prompts users to crave the drug and to continue use despite known adverse consequences. Therapy or group support may help; it helps to believe that addictions are controllable and that people can change. Although psychologists try to avoid overuse of the term *addiction* to label driven, excessive behaviors, there are some behavior addictions (such as gambling disorder and internet gaming disorder) in which behaviors become compulsive and dysfunctional.

10-3 What are *depressants*, and what are their effects?

Depressants, such as alcohol, *barbiturates*, and the *opioids*, reduce neural activity and slow body functions. Alcohol disinhibits, increasing the likelihood that we will act on our impulses, whether harmful or helpful. It also impairs judgment by slowing neural processing, disrupts memory processes by suppressing REM sleep, and reduces self-awareness and self-control. User expectations strongly influence alcohol's behavioral effects. Alcohol can shrink the brain in those with *alcohol use disorder* (marked by tolerance, withdrawal if use is suspended, and a drive to continue problematic use).

10-4 What are *stimulants*, and what are their effects?

Stimulants—including caffeine, nicotine, cocaine, the amphetamines, methamphetamine, and Ecstasy—excite neural activity and speed up body functions, triggering energy and mood changes. Stimulants can be highly addictive. *Nicotine's* effects make tobacco product use a difficult habit to kick, yet repeated attempts to quit seem to pay off. *Cocaine* gives users a fast high, followed shortly by a crash. Its risks include cardiac arrest, respiratory failure, convulsions, and emotional disturbances. *Amphetamines* stimulate neural activity, leading to heightened energy and mood. *Methamphetamine* use may permanently reduce dopamine production. *Ecstasy (MDMA)* is a combined stimulant and mild hallucinogen that produces euphoria and feelings of intimacy. Its users risk immune system suppression, permanent damage to

mood, memory impairment, and (if taken during physical activity) dehydration and escalating body temperatures.

10-5 What are *hallucinogens*, and what are their effects?

Hallucinogens, such as *LSD* and marijuana, distort perceptions and evoke hallucinations. The user's mood and expectations influence the effects of LSD, but common experiences are hallucinations and emotions varying from euphoria to panic. Marijuana's main ingredient, *THC*, may trigger feelings of disinhibition, euphoria, relaxation, relief from pain, and intense sensitivity to sensory stimuli, but may increase the risk of psychological disorders and lead to impaired attention, learning, and memory.

10-6 Why do some people become regular users of consciousness-altering drugs?

Some people may be biologically vulnerable to particular drugs. Psychological factors (such as stress, depression, and anxiety) and social factors (such as peer pressure and cultural influences) combine to lead many people to experiment with—and sometimes become addicted to—drugs. Cultural and ethnic groups have differing rates of drug use. Each type of influence—biological, psychological, and social-cultural—offers a possible path for drug misuse prevention and treatment programs.

Chapter 4 Nature, Nurture, and Human Diversity (Modules 11–13)

Module 11: Behavior Genetics: Predicting Individual Differences

11-1 What are *chromosomes, DNA, genes,* and the human *genome?* How do behavior geneticists explain our individual differences?

Genes are the biochemical units of *heredity* that make up *chromosomes,* the threadlike coils of *DNA*. When genes are expressed, they provide the code for creating the proteins that form our body's building blocks. The human *genome* is the shared genetic profile that distinguishes humans from other species, consisting at an individual level of all the genetic material in an organism's chromosomes. *Behavior geneticists* study the relative power and limits of genetic and *environmental* influences on behavior. Most of our differing traits are polygenic, and are influenced by the interaction of our individual environments with these genetic predispositions.

11-2 How do twin and adoption studies help us understand the effects and interactions of nature and nurture?

Studies of *identical (monozygotic) twins* versus *fraternal (dizygotic) twins*, separated twins, and biological versus adoptive relatives allow researchers to consider the effects of shared environment and shared genes, which sheds light on how nature and nurture influence our traits. Shared family environments have surprisingly little effect on personality, though parenting does influence other factors.

11-3 What have psychologists learned about temperament?

The stability of *temperament*, a person's characteristic emotional reactivity and intensity, from the first weeks of life suggests a genetic predisposition. The genetic effect appears in physiological differences such as heart rate and nervous system reactivity.

11-4 What is *heritability*, and how does it relate to individuals and groups?

Heritability is the proportion of variation among individuals in a group that can be attributed to genes. Heritable individual differences (in traits such as height or intelligence) need not imply heritable group differences. Genes mostly explain why some people are taller than others, but not why people are taller today than they were a century ago.

11-5 How is molecular genetics research changing our understanding of the effects of nature and nurture?

Our genetic predispositions and our specific environments *interact.* Environments can trigger genetic expression, and genetically influenced traits can influence the experiences we seek and the responses we evoke from others. *Molecular geneticists* study the molecular structure and function of genes, including those that affect behavior. One goal of *molecular behavior genetics* is to identify specific genes—or, more often, teams of genes—that together orchestrate complex traits (such as body weight, sexual orientation, and impulsivity) or put people at risk for disorders. The field of *epigenetics* studies the molecular mechanisms by which environments can trigger or block genetic expression.

Module 12: Evolutionary Psychology: Explaining Human Nature and Nurture

12-1 How do evolutionary psychologists use natural selection to explain behavior tendencies?

Evolutionary psychologists attempt to understand how *natural selection* has shaped traits and behavior tendencies found in all people. Genetic variations that increase the odds of reproducing and surviving in a particular environment are most likely to be passed on to future generations. Some variations arise from *mutations,* others from new gene combinations at conception. Humans share a genetic legacy and are predisposed to behaviors that promoted our

ancestors' survival and reproduction. Charles Darwin's theory of evolution is one of biology's fundamental organizing principles. He anticipated today's application of evolutionary principles in psychology.

12-2 How might an evolutionary psychologist explain male-female differences in sexuality and mating preferences?

Females tend to be more selective than males when choosing sexual partners. Evolutionary psychologists reason that male's attraction to multiple fertile-appearing partners increases their chances of spreading their genes widely. Because females incubate and nurse babies, they increase their own and their children's chances of survival by searching for mates with the potential for long-term investment in their joint offspring.

12-3 What are the key criticisms of evolutionary explanations of human sexuality, and how do evolutionary psychologists respond?

Critics argue that evolutionary psychologists start with an effect and work backward to an explanation, minimize contemporary social and cultural influences (including learned *social scripts*), and relieve people from taking responsibility for their sexual behavior, including sexual aggression. Evolutionary psychologists respond that they recognize the importance of social and cultural influences, but note the value of testable predictions based on evolutionary principles: Understanding our predispositions can help us overcome them.

Module 13: Cultural and Gender Diversity: Understanding Nature and Nurture

13-1 How do early experiences modify the brain?

The brain's nerve cells are sculpted by heredity and experience. As a child's brain develops, neural connections grow more numerous and complex. Experiences then prompt a pruning process, in which unused connections weaken and heavily used ones strengthen. Early childhood is an important period for shaping the brain, but thanks to neuroplasticity, the brain modifies itself throughout our lives in response to our learning.

13-2 In what ways do parents and peers shape children's development?

Family environment and parental expectations can affect children's motivation and future success. Personality, however, is mostly not attributable to the effects of nurture. As children attempt to fit in with peers, they tend to adopt their peers' culture.

13-3 How does culture affect our behavior?

A *culture* is an enduring set of behaviors, ideas, attitudes, values, and traditions shared by a group and transmitted from one generation to the next. Culture enables innovation and division of labor. Cultural *norms*, which differ across time and place, are understood rules that

inform members of a culture about accepted and expected behaviors. Cultures differ in how strictly people follow norms: People more often obey norms in *tight cultures*, but those in *loose cultures* expect greater variability.

13-4 How do individualist and collectivist cultures shape values and goals?

Our personality is culturally influenced. Although individuals vary, different cultures tend to emphasize either individualism or collectivism. Cultures based on self-reliant *individualism* tend to value personal independence and individual achievement. They define identity in terms of self-esteem, personal goals and attributes, and personal rights and liberties. Cultures based on socially connected *collectivism* tend to value group goals, social identity, and commitments. They define identity in terms of interdependence, tradition, and harmony.

13-5 How does the meaning of *gender* differ from the meaning of *sex?*

Gender refers to the behavioral characteristics that people associate with boy, girl, man, and woman. *Sex* refers to the biologically influenced characteristics by which people define *male, female,* and *intersex.* Our understanding of gender arises from the interplay between our biology and our experiences.

13-6 What are some of the ways males and females tend to be alike and to differ?

Whether male, female, or intersex, most of us receive 23 chromosomes from our mother and 23 from our father, of which 45 are unisex. Humans are in most ways alike, thanks to similar genetic makeup—they see, learn, and remember similarly, with comparable creativity, intelligence, and emotions. Male-female differences include age of onset of puberty, life expectancy, emotional expressiveness, and vulnerability to certain disorders. Men display more *aggression* than women do, and they are more likely to be physically (rather than *relationally*) aggressive. In most societies, men have more social power. Males tend to be more independent, while females tend to be more interdependent. Women often focus more on social connectedness than do men, and they "tend and befriend."

13-7 What factors contribute to gender bias in the workplace?

Workplace gender bias is revealed in differences in perception, compensation, and family-care responsibility. Social norms, interaction styles, and everyday behaviors also contribute. Men's leadership style tends to be directive, whereas women's tends to be more democratic. In their everyday behaviors and interactions, men tend to act more assertive and opinionated; women tend to act more supportive and apologetic.

13-8 How do sex hormones influence prenatal and adolescent sexual development?

Both sex chromosomes and sex hormones influence development. About seven weeks after conception, a gene on the *Y chromosome* from the father—who can contribute either this or an *X chromosome* (the mother always contributes the latter)—triggers the production of *testosterone*. This promotes male sex organ development. *Estrogens* contribute to female sex characteristics and are secreted in greater amounts by females than by males. During the fourth and fifth prenatal months, sex hormones bathe the fetal brain, with different patterns developing due to the male's greater testosterone and the female's estrogens. Prenatal exposure of females to unusually high levels of male hormones can later dispose them to more male-typical interests. Males prenatally exposed to low male hormone levels tend to grow up with more female-typical interests. Another flood of hormones occurs in *puberty*, triggering a growth spurt, the development of *primary* and *secondary sex characteristics*, and the landmark events of *menarche* and *spermarche*. Sexual development variations may occur through unusual combinations of male and female chromosomes, hormones, and anatomy.

13-9 What are some cultural influences on gender roles?

Gender roles—a set of expected behaviors, attitudes, and traits for men and women—vary across place and time. Gender roles in many parts of the world have changed dramatically in the last century.

Expectations about gender roles also influence cultural attitudes about *sexual aggression.*

13-10 What are the effects of sexual aggression? How have cultural views changed, and how can we reduce sexual aggression?

Sexual aggression, which includes sexual harassment and sexual assault, can increase anxiety, depression, and the risk of posttraumatic stress disorder; disrupt sleep; harm physical health; and make it difficult to trust new relationship partners. Cultural views of sexual aggression differ across time and place, with some cultures continuing to blame survivors, but changes in global norms over the last half-century have made such blaming less acceptable. Therapy for sexual aggressors has not proven effective, but we may reduce sexual aggression by encouraging people to report and share their experiences, empowering survivors, and educating communities about preventive bystander intervention strategies.

13-11 How do we form our gender identity?

Social learning theory proposes that we learn our *gender identity*—our personal sense of being male, female, neither, or some combination of male and female—in the same way that we learn other things: through reinforcement, punishment, and observation. But *gender typing* varies from child to child, indicating that imitation and reward, alone, do not explain gender identity. Some children organize themselves into "boy worlds" and "girl worlds"; others prefer *androgyny.* For people who identify as cisgender, gender

identity corresponds with birth-assigned sex. For those who identify as *transgender*, gender identity differs from what is typical for that person's birth-assigned sex. Gender identity is distinct from sexual orientation; transgender people may be sexually attracted to people of any gender or to no one at all.

13-12 How do nature, nurture, and our own choices influence gender roles and sexuality?

Individual development results from the interaction of biological, psychological, and social-cultural influences. Biological influences include our shared human genome; individual variations; prenatal environment; and sex-related genes, hormones, and physiology. Psychological influences include gene–environment interactions; the effect of early experiences on neural networks; responses evoked by our own characteristics, such as gender and temperament; and personal beliefs, feelings, and expectations. Social-cultural influences include parental and peer influences; cultural traditions and values; and cultural gender norms. And our individual choices affect the way all of these influences interact.

Chapter 5 Developing Through the Life Span (Modules 14–17)

Module 14: Developmental Issues, Prenatal Development, and the Newborn

14-1 What three issues have engaged developmental psychologists?

Developmental psychologists study physical, cognitive, and social changes across the life span. They often use *cross-sectional* (comparing people of different ages at one point in time) and *longitudinal studies* (retesting the same people over a period of years) to explore three issues: nature and nurture (the interaction between our genetic inheritance and our experiences); continuity and stages (which aspects of development are gradual and continuous and which change relatively abruptly); and stability and change (whether our traits endure or change as we age).

14-2 What is the course of prenatal development, and how do teratogens affect that development?

The life cycle begins at conception, when one sperm cell unites with an egg to form a *zygote.* The zygote's inner cells become the *embryo,*

and the outer cells become the placenta. In the next 6 weeks, body organs begin to form and function, and by 9 weeks, the *fetus* is recognizably human. *Teratogens* are potentially harmful agents that can pass through the placenta and harm the developing embryo or fetus, as happens with *fetal alcohol syndrome.*

14-3 What are some newborn abilities, and how do researchers explore infants' mental abilities?

Babies are born with sensory equipment and reflexes that facilitate their survival and their social interactions with adults. For example, they quickly learn to discriminate their mother's smell, and they prefer the sound of human voices. Researchers use techniques that test *habituation* to explore infants' abilities.

Module 15: Infancy and Childhood

15-1 During infancy and childhood, how do the brain and motor skills develop?

The brain's nerve cells are sculpted by heredity and experience. As a child's brain develops, neural connections grow more numerous and complex. Experiences then trigger a pruning process, in which unused connections weaken and heavily used ones strengthen. In childhood, complex motor skills—sitting, standing, walking—develop in a predictable sequence, though the timing of that sequence is a function of individual *maturation* and culture. We have few or no conscious memories of events occurring before about age

4. This infantile amnesia occurs in part because major brain areas have not yet matured.

15-2 How did Piaget broaden our understanding of the way a child's mind develops, and how have today's researchers built on his work?

As he studied children's *cognitive* development, Jean Piaget proposed that they actively construct and modify their understanding of the world through the processes of *assimilation* and *accommodation.* They form *schemas* that help them organize their experiences. Progressing from the simplicity of the *sensorimotor stage* of the first 2 years, in which they develop *object permanence*, children move to more complex ways of thinking. In the *preoperational stage* (about age 2 to about 6 or 7), children are *egocentric* and unable to perform simple logical operations. By about age 7, they enter the *concrete operational stage* and are able to comprehend the principle of *conservation.* By age 12, children enter the *formal operational stage* and can reason systematically. Research supports the sequence Piaget proposed, but it also shows that young children are more capable, and their development more continuous, than he believed.

15-3 How did Vygotsky view children's cognitive development?

Lev Vygotsky's studies of child development focused on the ways a child's mind grows by interacting with the social environment. In

his view, parents, teachers, and other children provide temporary *scaffolds* enabling children to step to higher levels of thinking.

15-4 What does it mean to develop a *theory of mind*, and how is this impaired in those with autism spectrum disorder?

Our *theory of mind — our* ideas about our own and others' mental states — develops during early childhood. Children with *autism spectrum disorder (ASD)* have an impaired theory of mind: They have difficulty understanding others' state of mind, as well as reflecting on their own.

15-5 How do caregiver-infant attachment bonds form?

At about 8 months, soon after object permanence develops, children separated from their caregivers display *stranger anxiety.* Infants form *attachments* with caregivers who gratify biological needs but, more importantly, who are comfortable, familiar, and responsive. Many birds and other animals have a more rigid attachment process, called *imprinting*, that occurs during a *critical period.*

15-6 How have psychologists studied attachment differences, and what have they learned?

Attachment has been studied in strange situation experiments, which show that some children are securely attached and others are insecurely (anxiously or avoidantly) attached. Infants' differing attachment styles reflect both their individual temperament and the

responsiveness of their parents and child-care providers. Adult relationships seem to reflect the attachment styles of early childhood, lending support to Erik Erikson's idea that *basic trust* is formed in infancy by our experiences with responsive caregivers.

15-7 How does experiencing adversity affect children's social development?

Most children growing up under adversity are resilient, and they may be hardier when facing future stresses. But extreme trauma in childhood may alter the brain, affecting our stress responses or leaving epigenetic marks. Children who experience neglect, bullying, poverty, wartime atrocities, or severe or prolonged abuse are at increased risk for health problems, psychological disorders, substance abuse, and criminality.

15-8 How do children's self-concepts develop?

Self-concept, an understanding and evaluation of who we are, emerges gradually. By 15 to 18 months, children recognize themselves in a mirror. By school age, they can describe many of their own traits and by age 8 or 10 their self-image is stable.

15-9 What are the four main parenting styles?

The main parenting styles are authoritarian (coercive), permissive (unrestraining), neglectful (uninvolved), and authoritative (confrontive).

15-10 What outcomes are associated with each parenting style?

Authoritative parenting is associated with greater self-esteem, self-reliance, self-regulation, and social competence; authoritarian parenting with lower self-esteem, less social skill, and a brain that overreacts to mistakes; permissive parenting with greater aggression and immaturity; and neglectful parenting with poor academic and social outcomes. However, correlation does not equal causation (it's possible that children with positive characteristics are more likely to bring out positive parenting methods).

Module 16: Adolescence and Emerging Adulthood

16-1 How is *adolescence* defined, and how do physical changes affect developing teens?

Adolescence is the transition period from childhood to adulthood, extending from *puberty* to social independence. Early maturation can be a challenge for developing adolescents. The brain's frontal lobes mature and myelin growth increases during adolescence and the early twenties, enabling improved judgment, impulse control, and long-term planning.

16-2 How did Piaget, Kohlberg, and later researchers describe adolescent cognitive and moral development?

Piaget theorized that adolescents develop a capacity for formal operations and that this development is the foundation for moral judgment. Lawrence Kohlberg proposed a stage theory of moral reasoning, from a preconventional morality of self-interest, to a conventional morality concerned with upholding laws and social rules, to (in some people) a postconventional morality of basic rights and self-defined ethical principles. Other researchers believe that morality lies in moral intuition and moral action as well as thinking. Kohlberg's critics note that the postconventional level is culturally limited (representing morality only from the perspective of an individualist society), and male-focused (since women more often emphasize care for those in need over what is "fair"). Life success can grow from the ability to delay gratification.

16-3 What are the social tasks and challenges of adolescence?

Erik Erikson proposed eight stages of psychosocial development across the life span. He believed we need to achieve trust, autonomy, initiative, competency, *identity* (in adolescence), *intimacy* (in young adulthood), generativity, and integrity. Each life stage has its own psychosocial task. Solidifying one's sense of self in adolescence means trying out a number of different roles. *Social identity* is the part of the self-concept that comes from a person's group memberships.

16-4 How do parents and peers influence adolescents?

During adolescence, parental influence diminishes and peer influence increases. Adolescents adopt their peers' ways of dressing, acting, and communicating. Positive parent-teen relationships correlate with positive peer relationships, however. Personalities and temperaments are shaped by both nature and nurture, including parental and peer influences.

16-5 What is *emerging adulthood?*

Due to earlier sexual maturity and later independence, the transition from adolescence to adulthood is taking longer than it once did. *Emerging adulthood* is the period from age 18 to the mid-twenties, when many young people are not yet fully independent. This stage is found mostly in today's Western cultures.

Module 17: Adulthood

17-1 What physical changes occur during middle and late adulthood?

Muscular strength, reaction time, sensory abilities, and cardiac output begin to almost imperceptibly decline in the mid-twenties; this downward trajectory accelerates through middle and late adulthood, varying considerably with personal health and exercise habits. Women's period of fertility ends with *menopause* around age 50; men experience a more gradual decline. In late adulthood, the immune system weakens, increasing susceptibility to life-threatening illnesses. But exercising can slow aging, enhancing

physical health as well as boosting memory, improving judgment, and reducing the risk of severe cognitive decline.

17-2 How does memory change with age?

Recall begins to decline, especially for meaningless information, but recognition memory remains strong. Developmental researchers study age-related changes such as in memory with cross-sectional studies and longitudinal studies. “Terminal decline” describes the cognitive decline in the final few years of life.

17-3 How do neurocognitive disorders and Alzheimer’s disease affect cognitive ability?

Neurocognitive disorders (NCDs) are acquired (not lifelong) disorders marked by cognitive deficits, which are often related to Alzheimer’s disease, brain injury or disease, or substance abuse. This damage to brain cells results in the erosion of mental abilities that is not typical of normal aging. *Alzheimer’s disease* causes the deterioration of memory, then reasoning. After 5 to 20 years, the person becomes emotionally flat, disoriented, disinhibited, incontinent, and finally mentally vacant.

17-4 What themes and influences mark our social journey from early adulthood to death?

Adults do not progress through an orderly sequence of age-related social stages. Chance events can determine life choices. The *social clock* is a culture’s preferred timing for events such as marriage,

parenthood, and retirement. Many people in Western cultures today feel freer about setting their own timing. Adulthood's dominant themes are love and work (Erikson's intimacy and generativity).

17-5 How does our well-being change across the life span?

Surveys show that until the very end, life satisfaction is unrelated to age. Positive emotions increase after midlife and negative ones decrease; with age come fewer extremes of emotion and mood. While older adults do have smaller social networks, with fewer friendships and greater loneliness, they also experience fewer relationship problems.

17-6 What range of reactions does a loved one's death trigger?

People do not grieve in predictable stages, as was once supposed, and bereavement therapy is not significantly more effective than grieving without such aid. Life can be affirmed even at death, especially for those who experience what Erikson called a sense of integrity—a feeling that one's life has been meaningful.

Chapter 6 Sensation and Perception (Modules 18–20)

Module 18: Basic Concepts of Sensation and Perception

18-1 What are *sensation* and *perception?* What do we mean by *bottom-up processing* and *top-down processing?*

Sensation is the process by which our *sensory receptors* and nervous system receive and represent stimulus energies from our environment. *Perception* is the process of organizing and interpreting this information, enabling recognition of meaningful objects and events. Sensation and perception are one continuous process. *Bottom-up processing* is sensory analysis that begins at the entry level, with information flowing from the sensory receptors to the brain. *Top-down processing* is information processing guided by high-level mental processes, as when we construct perceptions by filtering information through our experience and expectations.

18-2 What three steps are basic to all of our sensory systems?

Our senses (1) receive sensory stimulation, often using specialized receptor cells; (2) transform that stimulation into neural impulses; and (3) deliver the neural information to the brain. *Transduction* is

the process of converting energy into a form that our brain can use. Researchers in *psychophysics* study the relationships between stimuli's physical characteristics and our psychological experience of them.

18-3 How do *absolute thresholds* and *difference thresholds* differ?

Our *absolute threshold* for any stimulus is the minimum stimulation necessary for us to detect it 50 percent of the time. *Signal detection theory* predicts how and when we will detect a faint stimulus amid background noise. Individual absolute thresholds vary, depending on the strength of the signal and also on our experience, expectations, motivation, and alertness. Our *difference threshold* (also called the *just noticeable difference*, or *jnd*) is the minimum difference we can discern between two stimuli 50 percent of the time. *Weber's law* states that two stimuli must differ by a constant minimum percentage (not a constant amount) to be perceived as different.

18-4 How are we affected by subliminal stimulation?

We do sense some stimuli *subliminally*—less than 50 percent of the time—and can be affected by these sensations. But although we can be *primed*, subliminal sensations have no powerful, enduring influence.

18-5 What is the function of sensory adaptation?

Sensory adaptation (our diminished sensitivity to constant or routine odors, sounds, and touches) focuses our attention on informative changes in our environment.

18-6 How do our expectations, contexts, motivation, and emotions influence our perceptions?

Perceptual set is a mental predisposition that functions as a lens through which we perceive the world. Our learned concepts (schemas) prime us to organize and interpret ambiguous stimuli in certain ways. Our expectations, contexts, motivation, and emotions can color our interpretation of events and behaviors.

Module 19: Vision: Sensory and Perceptual Processing

19-1 What are the characteristics of the energy that we see as visible light? What structures in the eye help focus that energy?

What we see as light is only a thin slice of the broad spectrum of electromagnetic energy. The portion visible to humans extends from the shorter blue-violet wavelengths to the longer red light wavelengths. After entering the eye through the cornea, passing through the pupil and iris, and being focused by a lens, light energy particles strike the eye's inner surface, the *retina.* The *hue* we perceive in a light depends on its *wavelength,* and its brightness depends on its *intensity.*

19-2 How do the rods and cones process information, and what is the path information travels from the eye to the brain?

Light entering the eye triggers chemical changes that convert light energy into neural impulses. Photoreceptors called *cones* and *rods* at the back of the retina each provide a special sensitivity—cones to detail and color, rods to faint light and peripheral motion. After processing by bipolar and ganglion cells, neural impulses travel from the retina through the *optic nerve* to the thalamus, and on to the visual cortex. A lack of receptor cells at the point where the optic nerve leaves the eye creates a *blind spot* in the field of vision.

19-3 How do we perceive color in the world around us?

According to the *Young-Helmholtz trichromatic (three-color) theory*, the retina contains three types of color receptors. Contemporary research has found three types of cones, each most sensitive to the wavelengths of one of the three primary colors of light (red, green, or blue). According to Hering's *opponent-process theory*, there are three additional sets of opposing retinal processes (red-green, blue-yellow, black-white). Research has confirmed that, en route to the brain, neurons in the retina and the thalamus code the color-related information from the cones into pairs of opponent colors. These two theories, and the research supporting them, show that color processing occurs in two stages.

19-4 Where are feature detectors located, and what do they do?

Feature detectors, specialized nerve cells in the visual cortex, respond to specific features of the visual stimulus, such as shape, angle, or movement. Feature detectors pass information on to other cortical areas, where supercell clusters respond to more complex patterns.

19-5 How does the brain use parallel processing to construct visual perceptions?

Through *parallel processing*, the brain handles many aspects of vision (color, movement, form, and depth) simultaneously. Other neural teams integrate the results, comparing them with stored information and enabling perceptions.

19-6 How did the Gestalt psychologists understand perceptual organization, and how do figure-ground and grouping principles contribute to our perceptions?

Gestalt psychologists searched for rules by which the brain organizes fragments of sensory data into *gestalts*, or meaningful forms. In pointing out that the whole may exceed the sum of its parts, they noted that we filter sensory information and construct our perceptions. To recognize an object, we must first perceive it (see it as a *figure*) as distinct from its surroundings (the *ground*). We bring order and form to stimuli by organizing them into meaningful *groups*, following such rules as proximity, continuity, and closure.

19-7 How do binocular and monocular cues enable three-dimensional vision, and how does motion perception occur?

For those of us with vision, *depth perception* is the ability to see objects in three dimensions and to judge distance. The *visual cliff* and other research demonstrate that many species perceive the world in three dimensions at, or very soon after, birth. *Binocular cues*, such as *retinal disparity*, are depth cues that rely on information from both eyes. *Monocular cues* (such as relative height, relative size, relative motion, linear perspective, and interposition) let us judge depth using information transmitted by only one eye. The brain computes motion imperfectly, based partly on its assumption that shrinking objects are retreating and enlarging objects are approaching. A quick succession of images on the retina can create an illusion of movement, as in stroboscopic movement or the *phi phenomenon*.

19-8 How do perceptual constancies help us construct meaningful perceptions?

Perceptual constancies, such as in color, brightness (or lightness), shape, or size, enable us to perceive objects as stable despite the changing image they cast on our retinas. Our brain constructs our experience of an object's color or brightness through comparisons with other surrounding objects. Knowing an object's size gives us clues to its distance; knowing its distance gives clues about its size, but we sometimes misread monocular distance cues and reach the wrong conclusions, as in the Moon illusion.

19-9 What does research on restored vision, sensory restriction, and perceptual adaptation reveal about the effects of experience on perception?

Experience guides our perceptual interpretations. People blind from birth who gain sight after surgery lack the experience to visually recognize shapes and forms. Sensory restriction research indicates that there is a critical period for some aspects of sensory and perceptual development. Without early stimulation, the brain's neural organization does not develop normally. People given glasses that shift the world slightly to the left or right, or even upside down, experience *perceptual adaptation*. They are initially disoriented, but they manage to adapt to their new context.

Module 20: Hearing, Skin, Chemical, and Body Senses

20-1 What are the characteristics of the air pressure waves that we hear as sound?

Sound waves are bands of compressed and expanded air. Our ears detect these changes in air pressure and transform them into neural impulses, which the brain decodes as sound. Sound waves vary in amplitude, which we perceive as differing loudness (with sound intensity measured in decibels), and in *frequency* (measured in hertz), which we experience as differing *pitch*.

20-2 How does the ear transform sound energy into neural messages?

The *middle ear* is the chamber between the eardrum and cochlea; the *inner ear* consists of the cochlea, semicircular canals, and vestibular sacs. Sound waves traveling through the auditory canal cause tiny vibrations in the eardrum. The bones of the middle ear amplify the vibrations and relay them to the fluid-filled cochlea. Rippling of the basilar membrane, caused by pressure changes in the cochlear fluid, causes movement of the tiny hair cells, triggering neural messages to be sent (via the thalamus) to the auditory cortex in the brain. *Sensorineural hearing loss* (or nerve deafness) results from damage to the cochlea's hair cells or their associated nerves. *Conduction hearing loss* results from damage to the mechanical system that transmits sound waves to the cochlea. *Cochlear implants* can restore hearing for some people.

20-3 How do we detect loudness, discriminate pitch, and locate sounds?

Loudness is not related to the intensity of a hair cell's response, but rather to the number of activated hair cells. *Place theory* (place coding) explains how we hear high-pitched sounds, and *frequency theory* (temporal coding) extended by the volley principle explains how we hear low-pitched sounds. A combination of the two theories explains how we hear pitches in the middle range. Sound waves strike one ear sooner and more intensely than the other. To locate

sounds, the brain analyzes the minute differences in the sounds received by the two ears and computes the sound's source.

20-4 What are the four basic touch sensations, and how do we sense touch?

Our sense of touch is four basic sensations—pressure, warmth, cold, and pain—that combine to produce other sensations, such as "itchy" or "wet."

20-5 What biological, psychological, and social-cultural influences affect our experience of pain? How do placebos, distraction, and hypnosis help control pain?

The biopsychosocial perspective views our perception of pain as the sum of biological, psychological, and social-cultural influences. Pain reflects bottom-up sensations and top-down processes. One theory of pain is that a *"gate"* in the spinal cord either opens to permit pain signals traveling up small nerve fibers to reach the brain, or closes to prevent their passage. Pain treatments often combine physical and psychological elements. Combining a placebo with distraction, and amplifying the effect with *hypnosis* (which increases our response to suggestions), can help relieve pain. *Posthypnotic suggestion* is used by some clinicians to control undesired symptoms and behavior.

20-6 In what ways are our senses of taste and smell similar, and how do they differ?

Taste and smell are both chemical senses. Taste *(gustation)* is a composite of five basic sensations—sweet, sour, salty, bitter, and umami—and of the aromas that interact with information from the taste receptor cells of the taste buds. There are no basic sensations for smell *(olfaction).* From the top of each nasal cavity, some 20 million olfactory receptor cells for smell send messages to the brain's olfactory bulb and then onward to the temporal lobe's primary smell cortex and to the parts of the limbic system involved in memory and emotion.

20-7 How do we sense our body's position and movement?

Position and motion sensors in muscles, tendons, and joints called proprioceptors enable *kinesthesia*, our sense of the position and movement of our body parts. We monitor our head's (and thus our body's) position and movement, and maintain our balance, with our *vestibular sense*, which relies on the semicircular canals and vestibular sacs to sense the tilt or rotation of our head.

20-8 How does *sensory interaction* influence our perceptions, and what is *embodied cognition?*

Our senses influence one another. This *sensory interaction* occurs, for example, when the smell of a favorite food amplifies its taste. *Embodied cognition* is the influence of bodily sensations, gestures, and other states on cognitive preferences and judgments.

20-9 What are the claims of ESP, and what have most research psychologists concluded after putting these claims to the test?

Parapsychology is the study of paranormal phenomena, including *extrasensory perception (ESP)* and psychokinesis. The three most testable forms of ESP are telepathy (mind-to-mind communication), clairvoyance (perceiving remote events), and precognition (perceiving future events). To refute those who say there is no ESP, one need only produce a single person who can demonstrate a single, reproducible ESP event. Although study continues, researchers have been unable to replicate ESP phenomena under controlled conditions.

Chapter 7 Learning (Modules 21–23)

Module 21: Basic Learning Concepts and Classical Conditioning

21-1 How do we define *learning*, and what are some basic forms of learning?

Learning is the process of acquiring through experience new and relatively enduring information or behaviors. In *associative learning*, we learn that certain events occur together. In classical conditioning, we learn to associate two *stimuli* and thus to anticipate events. Automatically responding to stimuli we do not control is called *respondent behavior.* In operant conditioning, we learn to associate a response and its consequence. These associations produce *operant behaviors.* Through *cognitive learning*, we acquire mental information that guides our behavior. For example, in observational learning, we learn new behaviors by observing events and watching others.

21-2 What is behaviorism's view of learning?

Ivan Pavlov's work on classical conditioning laid the foundation for *behaviorism*, the view that psychology should be an objective science

that studies behavior without reference to mental processes. The behaviorists believed that the basic laws of learning are the same for all species, including humans.

21-3 Who was Pavlov, and what are the basic components of classical conditioning?

Ivan Pavlov, a Russian physiologist, created novel experiments on learning. His early twentieth-century research over the last three decades of his life demonstrated that classical conditioning is a basic form of learning. *Classical conditioning* is a type of learning in which an organism comes to associate stimuli and anticipate events. A *UR* (unconditioned response) is an event that occurs naturally (such as salivation), in response to some stimulus. A *US* (unconditioned stimulus) is something that naturally and automatically (without learning) triggers the unlearned response (as food in the mouth triggers salivation). A *CS* (conditioned stimulus) is originally an *NS* (neutral stimulus, such as a tone) that, after association with a US (such as food) comes to trigger a CR. A *CR* (conditioned response) is the learned response (salivating) to the originally neutral (but now conditioned) stimulus.

21-4 In classical conditioning, what are the processes of *acquisition, extinction, spontaneous recovery, generalization,* and *discrimination?*

In classical conditioning, the first stage is *acquisition*, associating an NS with the US so that the NS begins triggering the CR. Acquisition occurs most readily when the NS is presented just before (ideally, about a half-second before) a US, preparing the organism for the upcoming event. This finding supports the view that classical conditioning is biologically adaptive. *Extinction* is diminished responding, which occurs if the CS appears repeatedly by itself without the US. *Spontaneous recovery* is the reappearance of a weakened conditioned response, following a rest period. *Generalization* is the tendency to respond to stimuli that are similar to a CS. *Discrimination* is the learned ability to distinguish between a CS and other irrelevant stimuli.

21-5 Why does Pavlov's work remain so important?

Pavlov taught us that significant psychological phenomena can be studied objectively and that classical conditioning is a basic form of learning that applies to all species.

21-6 What have been some applications of Pavlov's work to human health and well-being? How did Watson apply Pavlov's principles to learned fears?

Classical conditioning techniques are used to improve human health and well-being in many areas, including behavioral therapy for some types of psychological disorders. The body's immune system may also respond to classical conditioning. Pavlov's work also provided a basis for Watson's idea that human emotions and

behaviors, though biologically influenced, are mainly a bundle of conditioned responses. Watson applied classical conditioning principles in his studies of "Little Albert" to demonstrate how specific fears might be conditioned.

Module 22: Operant Conditioning

22-1 What is *operant conditioning?*

Operant conditioning is a type of learning in which behavior becomes more likely to recur if followed by a reinforcer or less likely to recur if followed by a punisher.

22-2 Who was Skinner, and how is operant behavior reinforced and shaped?

B. F. Skinner was a college English major and aspiring writer who later entered graduate school for psychology. He became modern behaviorism's most influential and controversial figure. Expanding on Edward Thorndike's *law of effect*, Skinner and others found that the behavior of rats or pigeons placed in an *operant chamber* (Skinner box) can be *shaped* by using reinforcers to guide successive approximations of the desired behavior.

22-3 How do positive and negative reinforcement differ, and what are the basic types of reinforcers?

Reinforcement is any event that strengthens the behavior it follows. *Positive reinforcement* adds a desirable stimulus to increase the frequency of a behavior. *Negative reinforcement* reduces or removes an aversive stimulus to increase the frequency of a behavior. *Primary reinforcers* (such as receiving food when hungry or having nausea end during an illness) are innately satisfying—no learning is required. *Conditioned* (or secondary) *reinforcers* (such as money) are satisfying because we have learned to associate them with more basic rewards (such as the desirable things we buy). Immediate reinforcers (such as a food reward given right after a desired behavior) offer immediate payback; delayed reinforcers (such as a paycheck) require the ability to delay gratification.

22-4 How do different reinforcement schedules affect behavior?

A *reinforcement schedule* defines how often a response will be reinforced. In *continuous reinforcement* (reinforcing desired responses every time they occur), learning is rapid, but so is extinction if rewards cease. In *partial (intermittent) reinforcement* (reinforcing responses only sometimes), initial learning is slower, but the behavior is much more resistant to extinction. *Fixed-ratio schedules* reinforce behaviors after a set number of responses; *variable-ratio schedules*, after an unpredictable number. *Fixed-interval schedules* reinforce behaviors after set time periods; *variable-interval schedules*, after unpredictable time periods.

22-5 How does punishment differ from negative reinforcement, and how does punishment affect behavior?

Punishment aims to decrease the frequency of a behavior (such as a child's disobedience). Positive punishment administers, or adds, an undesirable consequence (such as a speeding ticket) or withdraws something desirable (such as taking away a favorite toy). Negative punishment aims to increase the frequency of a behavior (such as putting on your seat belt) by withdrawing, or subtracting, something undesirable (the annoying beeping).

This desired consequence (silencing the annoying beeping) increases the likelihood that the behavior (putting on your seat belt) will be repeated. Physical punishment can have undesirable side effects, such as suppressing rather than changing unwanted behaviors, failing to provide a direction for appropriate behavior, encouraging discrimination (so that the undesirable behavior appears when the punisher is not present), creating fear, and teaching aggression.

22-6 Why did Skinner's ideas provoke controversy, and how might his operant conditioning principles be applied?

Critics of Skinner's principles believed the approach dehumanized people by neglecting their personal freedom and seeking to control their actions. Skinner replied that people's actions are already controlled by external consequences and that reinforcement is more humane than punishment as a means for controlling behavior.

Teachers can use shaping techniques to guide students' behaviors and use interactive media such as online adaptive quizzing to provide immediate feedback. (The LearningCurve adaptive quizzing system available with this text provides such feedback and allows students to direct the pace of their own learning.) Coaches can build players' skills and self-confidence by rewarding small improvements. Computer programmers and game developers can use reinforcement principles to train artificial intelligence (AI) machines that simulate human learning. Managers can boost productivity and morale by rewarding well-defined and achievable behaviors. Parents can reward desired behaviors but not undesirable ones. We can shape our own behaviors by stating realistic goals, planning how to work toward those goals, monitoring the frequency of desired behaviors, reinforcing desired behaviors, and gradually reducing rewards as behaviors become habitual.

22-7 How does operant conditioning differ from classical conditioning?

In operant conditioning, an organism learns associations between its own behavior and resulting events; this form of conditioning involves operant behavior (behavior that operates on the environment, producing rewarding or punishing consequences). In classical conditioning, the organism forms associations between stimuli—events it does not control; this form of conditioning involves respondent behavior (automatic responses to some stimulus).

Module 23: Biology, Cognition, and Learning

23-1 How do biological constraints affect classical and operant conditioning?

An animal's capacity for conditioning is limited by biological constraints, so some associations are easier to learn. Each species has a biological predisposition to learn associations that aid its survival—a phenomenon called *preparedness*. Those who readily learned taste aversions were unlikely to eat the same toxic food again and were more likely to survive and leave descendants. Nature constrains each species' capacity for both classical conditioning and operant conditioning. Our preparedness to associate a CS with a US that follows predictably and immediately is often (but not always) adaptive. During operant training, animals may display *instinctive drift* by reverting to biologically predisposed patterns.

23-2 How do cognitive processes affect classical and operant conditioning?

In classical conditioning, animals may learn when to expect a US and may be aware of the link between stimuli and responses. In operant conditioning, *cognitive mapping* and *latent learning* research demonstrate the importance of cognitive processes in learning.

23-3 What is *observational learning?*

Observational learning (also called *social learning*) involves learning by watching and imitating, rather than through direct experience.

23-4 How may observational learning be enabled by neural mirroring?

Our brain's frontal lobes have a demonstrated ability to mirror the activity of another's brain, which may enable imitation and observational learning. Some scientists argue that *mirror neurons* are responsible for this ability, while others attribute it to distributed brain networks.

23-5 What is the impact of prosocial modeling and of antisocial modeling?

Children tend to imitate what a model does and says, whether the behavior being *modeled* is *prosocial* (positive, constructive, and helpful) or antisocial. If a model's actions and words are inconsistent, children may imitate the hypocrisy they observe.

23-6 What is the violence-viewing effect?

Media violence can contribute to aggression. This violence-viewing effect may be prompted by imitation and desensitization. Correlation does not equal causation, but study participants have reacted more cruelly to provocations when they have viewed violence (instead of entertaining nonviolence).

Chapter 8 Memory (Modules 24–26)

Module 24: Studying and Encoding Memories

24-1 What is *memory*, and how is it measured?

Memory is learning that has persisted over time, through the encoding, storage, and retrieval of information. Evidence of memory may be seen in an ability to *recall* information, *recognize* it, or *relearn* it more easily on a later attempt. Psychologists can measure these different forms of memory separately.

24-2 How do memory models help us study memory, and how has later research updated the three-stage information-processing model?

Psychologists use memory models to think about and explain how our brain forms and retrieves memories. Information-processing models involve three processes: *encoding, storage*, and *retrieval.* Our agile brain processes many things simultaneously by means of *parallel processing.* The connectionism information-processing model focuses on this multitrack processing, viewing memories as products of interconnected neural networks. The three processing stages in the Atkinson-Shiffrin model are *sensory memory, short-term*

memory, and *long-term memory*. This model has since been updated to include newer concepts, such as working memory (the active "scratch pad" processing that occurs at the stage when our short-term memories combine with our long-term memories) and *automatic processing* (which occurs behind the scenes to allow information to slip into long-term memory without the need to consciously attend to it).

24-3 How do explicit and implicit memories differ?

The human brain processes information on dual tracks, consciously and unconsciously. Many *explicit* (declarative) *memories — our* conscious memories of facts and experiences — form through *effortful processing*, which requires conscious effort and attention. *Implicit* (nondeclarative) *memories — of* learned skills and classically conditioned associations — happen without our awareness, through *automatic processing*.

24-4 What information do we process automatically?

In addition to skills and classically conditioned associations, we automatically process incidental information about space, time, and frequency and familiar or well-learned information, such as sounds, smells, and word meanings.

24-5 How does sensory memory work?

Sensory memory feeds some information into working memory for active processing there. An *iconic memory* is a very brief (a few tenths of a second) sensory memory of visual stimuli; an *echoic memory* is a three- or four-second sensory memory of auditory stimuli.

24-6 What is our short-term memory capacity?

Short-term memory capacity is about seven bits of information, plus or minus two, but this information disappears from memory quickly without rehearsal. Our working memory capacity for active processing varies, depending on age and other factors, but everyone does better and more efficient work by avoiding task-switching.

24-7 What are some effortful processing strategies that can help us remember new information?

Effective effortful processing strategies include *chunking, mnemonics,* and hierarchies. Each boosts our ability to form new memories.

24-8 How do distributed practice, deep processing, and making new material personally meaningful aid memory?

Distributed practice sessions (the *spacing effect*) produce better long-term recall. The *testing effect* is the finding that consciously

retrieving, rather than simply rereading, information enhances memory. Depth of processing also affects long-term retention. In *shallow processing*, we encode words based on their structure or sound. Retention is best when we use *deep processing*, encoding words based on their meaning. We also more easily remember material when we learn and rephrase it into personally meaningful terms — the self-reference effect.

Module 25: Storing and Retrieving Memories

25-1 What is the capacity of long-term memory? Are our long-term memories processed and stored in specific locations?

Our long-term memory capacity is essentially unlimited. Memories are not stored intact in the brain in single spots. Many parts of the brain interact as we encode, store, and retrieve memories.

25-2 What roles do the frontal lobes and hippocampus play in memory processing?

The frontal lobes and *hippocampus* are parts of the brain network dedicated to explicit memory formation. Many brain regions send information to the frontal lobes for processing. The hippocampus, with the help of nearby brain networks, registers and temporarily holds elements of explicit memories (which are either *semantic* or

episodic) before moving them to other brain regions for long-term storage. The neural storage of long-term memories, which is supported by sleep, is called *memory consolidation.*

25-3 What roles do the cerebellum and basal ganglia play in memory processing?

The cerebellum and basal ganglia are parts of the brain network dedicated to implicit memory formation. The cerebellum is important for storing classically conditioned memories. The basal ganglia are involved in motor movement and help form procedural memories for skills. Many reactions and skills learned during our first 4 years continue into our adult lives, although we cannot consciously remember learning these associations and skills (infantile amnesia).

25-4 How do emotions affect our memory processing?

Emotional arousal causes an outpouring of stress hormones, which leads the amygdala to boost activity in the brain's memory-forming areas. Significantly stressful events can trigger very clear *flashbulb memories.* Through rehearsal, memory of personally important experiences largely endures.

25-5 How do changes at the synapse level affect our memory processing?

Long-term potentiation (LTP) is the neural basis for learning and memory. In LTP, neurons become more efficient at releasing and sensing the presence of neurotransmitters, and more connections develop between neurons.

25-6 How do external cues, internal emotions, and order of appearance influence memory retrieval?

External cues activate associations that help us retrieve memories; this process may occur without our awareness, as it does in *priming*. The *encoding specificity principle* is the idea that cues and contexts specific to a particular memory will be most effective in helping us recall it. Returning to the same physical context or emotional state *(mood congruency)* in which we formed a memory can help us retrieve it. The *serial position effect* is our tendency to recall best the last items (which may still be in working memory) and the first items (which we've spent more time rehearsing) in a list.

Module 26: Forgetting, Memory Construction, and Improving Memory

26-1 Why do we forget?

Some people experience *anterograde amnesia,* an inability to form new memories, or *retrograde amnesia,* an inability to retrieve old memories. Normal forgetting can happen because we have never

encoded information (encoding failure); because the physical memory trace has decayed (storage decay); or because we cannot retrieve what we have encoded and stored (retrieval failure). Retrieval problems may result from *proactive* (forward-acting) *interference,* when prior learning interferes with recall of new information, or from *retroactive* (backward-acting) *interference,* when new learning disrupts recall of old information. Motivated forgetting occurs, but researchers have found little evidence of *repression.*

26-2 How do misinformation, imagination, and source amnesia influence our memory construction? How do we decide whether a memory is real or false?

Memories can be continually revised when retrieved, a process memory researchers call *reconsolidation. The misinformation effect* (exposure to misleading information) and imagination inflation may corrupt our stored memories of what actually happened. When we reassemble a memory during retrieval, we may attribute it to the wrong source *(source amnesia).* Source amnesia may help explain *déjà vu.* Since memory involves reconstruction as well as reproduction, and the misinformation effect and source amnesia occur outside our awareness, it is difficult to separate false memories from real ones.

26-3 Why have reports of repressed and recovered memories been so hotly debated?

The debate focuses on whether memories of early childhood abuse are repressed and can be recovered during therapy. Unless the victim was a child too young to remember, such traumas are usually remembered vividly, not repressed. Psychologists agree that childhood sexual abuse happens; injustice happens; forgetting happens; recovered memories are common; memories of events that happened before age 4 are unreliable; memories "recovered" under hypnosis are especially unreliable; and memories, whether real or false, can be emotionally upsetting.

26-4 How reliable are young children's eyewitness descriptions?

Children's eyewitness descriptions are subject to the same memory influences that distort adult reports, and suggestive interviewing techniques can lead to false memories. But if questioned by a carefully trained interviewer who asks nonleading questions — and especially if they have not spoken to involved adults prior to the interview — children can accurately recall events and people involved in them.

26-5 How can you use memory research findings to do better in this and other courses?

Memory research findings suggest the following strategies for improving memory: Rehearse repeatedly, make the material meaningful, activate retrieval cues, use mnemonic devices, minimize proactive and retroactive interference, sleep more, and

test yourself to be sure you can retrieve, as well as recognize, material.

Chapter 9 Thinking and Language (Modules 27–28)

Module 27: Thinking

27-1 What are *cognition* and *metacognition*, and what are the functions of concepts?

Cognition refers to all the mental activities associated with thinking, knowing, remembering, and communicating. *Metacognition* is cognition about our cognition or keeping track of and evaluating our mental processes. We use *concepts*, mental groupings of similar objects, events, ideas, or people, to simplify and order the world around us. We form most concepts around *prototypes* or best examples of a category.

27-2 What cognitive strategies assist our problem solving, and what obstacles hinder it?

An *algorithm* is a methodical, logical rule, or procedure (such as a step-by-step description for evacuating a building during a fire) that guarantees a solution to a problem. A *heuristic* is a simpler strategy—a mental shortcut (such as running for an exit if you smell smoke)—that is usually speedier than an algorithm but is also more error prone. *Insight* is not a strategy-based solution but rather a sudden flash of inspiration that solves a problem. Obstacles to problem

solving include *confirmation bias*, which predisposes us to verify rather than challenge our preconceptions, and *fixation*, which may prevent us from taking the fresh perspective that would lead to a solution.

27-3 What is *intuition*, and how can the representativeness and availability heuristics influence our decisions and judgments?

Intuition is the effortless, immediate, automatic feelings, or thoughts, we often use instead of systematic reasoning. Heuristics enable snap judgments. Using the *representativeness heuristic*, we judge the likelihood of events based on how well they seem to represent particular prototypes. Using the *availability heuristic*, we judge the likelihood of things based on how readily they come to mind.

27-4 What factors exaggerate our fear of unlikely events?

We tend to be afraid of what our ancestral history has prepared us to fear, what we cannot control, what is immediate, and what is most readily available in memory. We fear too little the ongoing threats that claim lives one by one, such as traffic accidents and diseases.

27-5 How are our decisions and judgments affected by overconfidence, belief perseverance, and framing?

Overconfidence can lead us to overestimate the accuracy of our beliefs. When a belief we have formed and explained has been

discredited, *belief perseverance* may cause us to cling to that belief. A remedy for belief perseverance is to consider how we might have explained an opposite result. *Framing* is the way an issue is posed. Subtle differences in presentation can dramatically alter our responses and *nudge* us toward particular decisions.

27-6 How do smart thinkers use intuition?

Smart thinkers welcome their intuitions (which are usually adaptive) but also know when to override them. When making complex decisions we may benefit from gathering as much information as possible and then taking time to let our two-track mind process it.

27-7 What is *creativity*, and what fosters it?

Creativity, the ability to produce novel and valuable ideas, is supported by a certain level of aptitude but is more than what intelligence tests reveal. Aptitude tests require *convergent thinking*, but creativity requires *divergent thinking.* Robert Sternberg has proposed that creativity involves expertise; imaginative thinking skills; a venturesome personality; intrinsic motivation; and a creative environment that sparks, supports, and refines creative ideas.

27-8 What do we know about thinking in other species?

Researchers make inferences about other species' consciousness and intelligence based on behavior and neural activity. Evidence

from studies of various species shows that many other animals use concepts, numbers, and tools and that they transmit learning from one generation to the next (cultural transmission). And, like humans, some other species show insight, self-awareness, altruism, cooperation, and grief.

Module 28: Language and Thought

28-1 What are the structural components of a language?

Phonemes are a *language's* basic units of sound. *Morphemes* are the elementary units of meaning. *Grammar*—the system of rules that enables us to communicate—includes semantics (rules for deriving meaning from sounds) and *syntax* (rules for ordering words into sentences).

28-2 How do we acquire language, and what did Chomsky mean by *universal grammar?*

As our biology and experience interact, we readily learn the specific grammar and vocabulary of the language we experience as children. Linguist Noam Chomsky has proposed that humans are born with a built-in predisposition to learn grammar rules, which he called universal grammar. Human languages do share some commonalities, but other researchers note that children learn grammar as they discern language patterns.

28-3 What are the milestones in language development, and when is the critical period for acquiring language?

Language development's timing varies, but all children follow the same sequence. Receptive language (the ability to understand what is said to or about you) develops before productive language (the ability to produce words). At about 4 months of age, infants *babble*, making sounds found in languages from all over the world, which by about 10 months includes only the sounds found in their household language. Around 12 months of age, children begin to speak in single words. This *one-word stage* evolves into *two-word* and other short, *telegraphic* utterances before their second birthday, after which they begin speaking in full sentences. Childhood is a critical period for learning language. Children who get a late start on language learning follow the usual developmental sequence, though at a faster pace. But children not exposed to either a spoken or a signed language until age 7 will never be able to fully comprehend or use any language. The importance of early language experiences is often evident in deaf children born to hearing-nonsigning parents.

28-4 What brain areas are involved in language processing and speech?

Aphasia is an impairment of language, usually caused by left-hemisphere damage. Two important language- and speech-processing areas are *Broca's area*, a region of the left frontal lobe that

controls language expression, and *Wernicke's area,* a region in the left temporal lobe that controls language reception. Language processing is spread across other brain areas as well, with different neural networks handling specific linguistic subtasks.

28-5 What is the relationship between thinking and language, and what is the value of thinking in images?

Although Benjamin Lee Whorf's *linguistic determinism* hypothesis suggested that language determines thought, it is more accurate to say that language influences thought *(linguistic relativism).* Different languages embody different ways of thinking, and bilingualism can enhance thinking. We often think in images when we use implicit (nondeclarative, procedural) memory. Thinking in images can increase our skills when we mentally practice an activity. Process simulation (focusing on the steps needed to reach a goal) is effective, but outcome simulation (fantasizing about having achieved the goal) does little.

28-6 What do we know about other species' capacity for language?

Chimpanzees and bonobos have learned to communicate with humans by signing or by pushing buttons. Some have developed vocabularies of nearly 400 words, communicated by stringing these words together, and have demonstrated some understanding of syntax. While only humans communicate in complex sentences, other animals' impressive abilities to think and communicate

challenge humans to consider what this means about the moral rights of other species.

Chapter 10 Intelligence (Modules 29–31)

Module 29: What Is Intelligence?

29-1 How do psychologists define *intelligence?*

Intelligence is the ability to learn from experience, solve problems, and use knowledge to adapt to new situations.

29-2 What are the arguments for *g?*

Charles Spearman proposed that we have one *general intelligence (g)* underlying all other specific mental abilities. Through his work with factor analysis, a statistical procedure that identifies clusters of related variables, he noted that those who score high in one area typically score higher than average in other areas.

29-3 How have the concepts of *fluid intelligence* and *crystallized intelligence,* and the *CHC theory,* affected our understanding of intelligence?

Raymond Cattell and John Horn formulated a theory of general ability based on two factors: *fluid intelligence (Gf)* and *crystallized intelligence (Gc).* The *Cattell-Horn-Carroll (CHC) theory* affirms a general intellectual ability factor, but also identifies more specific

abilities (such as reading and writing ability, memory capacity, and processing speed).

29-4 How do Gardner's and Sternberg's theories of multiple intelligences differ, and what criticisms have they faced?

Howard Gardner proposed eight relatively independent intelligences (linguistic, logical-mathematical, musical, spatial, bodily kinesthetic, intrapersonal, interpersonal, and naturalist), as well as a possible ninth (existential intelligence). The different intelligences of people with *savant syndrome* and certain kinds of brain damage seem to support this view. Robert Sternberg's triarchic theory proposes three intelligence areas that contribute to life success: analytical (academic problem solving), creative (innovative smarts), and practical (required for everyday tasks). Critics note that research has confirmed a general intelligence factor, which widely predicts performance. Highly successful people also tend to be conscientious and doggedly energetic; their achievements arise from both ability *and* deliberate practice.

29-5 What are the four components of emotional intelligence?

Emotional intelligence, which is an aspect of social intelligence, includes the abilities to perceive, understand, manage, and use emotions. Emotionally intelligent people tend to be happy, healthy, and more successful personally and professionally.

Module 30: Intelligence Assessment and Dynamics

30-1 What is an *intelligence test*, and how do *achievement tests* and *aptitude tests* differ?

An *intelligence test* assesses a person's mental aptitudes and compares them with those of others, using numerical scores. *Aptitude tests* measure the ability to learn, while *achievement tests* measure what has already been learned.

30-2 When and why were intelligence tests created, and how do today's tests differ from early intelligence tests?

Francis Galton, who was fascinated with measuring what he believed to be hereditary genius (so that those with exceptional abilities might be encouraged to reproduce), attempted but failed to construct a simple intelligence test in the late 1800s. Alfred Binet, who tended toward an environmental explanation of intelligence differences, started the modern intelligence-testing movement in France in the early 1900s, when he developed questions to help predict children's future progress in the Paris school system. Binet hoped his test, which measured children's *mental age*, would improve children's education; but he feared it might also be used to label children. During the early twentieth century, Lewis Terman of Stanford University revised Binet's work for use in the United States. Terman thought his *Stanford-Binet* could help guide people toward

appropriate opportunities, but his belief that intelligence was fixed at birth and differed among ethnic groups realized Binet's fear that intelligence tests would be used to limit children's opportunities. William Stern contributed the concept of the *IQ (intelligence quotient).* The most widely used intelligence tests today are the *Wechsler Adult Intelligence Scale (WAIS)* and Wechsler's tests for children. These tests differ from their predecessors by offering an overall intelligence score as well as scores for verbal comprehension, perceptual reasoning, working memory, and processing speed.

30-3 What is a *normal curve*, and what does it mean to say that a test has been *standardized* and is *reliable* and *valid?*

The distribution of test scores often forms a *normal* (bell-shaped) *curve* around the central average score, with fewer and fewer scores at the extremes. *Standardization* establishes a basis for meaningful score comparisons by giving a test to a representative sample of future test-takers. *Reliability* is the extent to which a test yields consistent results (on two halves of the test, on alternative forms of the test, or on retesting). *Validity* is the extent to which a test measures or predicts what it is supposed to. A test has *predictive validity* if it predicts a behavior it was designed to predict. (Aptitude tests have predictive validity if they can predict future achievements; their predictive power is best for the early school years.)

30-4 What are the traits of those at the low and high intelligence extremes?

People who score at the two extremes of the normal curve differ noticeably in intelligence test performance. An intelligence test score of or below 70 is one diagnostic factor in the diagnosis of intellectual developmental disorder; limited conceptual, social, and practical skills are other factors. People at the high intelligence extreme—such as those with IQ scores of over 135 whom Terman studied—tend to be healthy and well adjusted, as well as unusually successful academically. "Gifted" and "remedial" programs may create self-fulfilling prophecies, but can be effective when students are appropriately placed.

30-5 What are *cross-sectional studies* and *longitudinal studies*, and why is it important to know which method was used?

Cross-sectional studies, which study people of different ages at the same point in time, compare people of different eras and life circumstances. This can provide an excellent snapshot of a particular moment, but *longitudinal studies*—which follow and retest the same people over time—are superior for tracing the evolution of traits over a longer period. When studying intelligence, psychologists using the cross-sectional method concluded that mental ability declines with age, but those using the longitudinal method learned that it remains stable (or even increases).

30-6 How stable are intelligence test scores over the life span?

The stability of intelligence test scores increases with age. At age 4, scores begin to predict adolescent and adult scores. By age 11, scores are very stable and predictive.

30-7 How does aging affect crystallized intelligence *(Gc)* and fluid intelligence *(Gf)?*

The answers to age-and-intelligence questions depend on what we assess and how we assess it. Fluid intelligence *(Gf)* declines in older adults, who lose recall memory and processing speed; but accumulated knowledge, reflected in crystallized intelligence *(Gc)*, tends to increase with age.

Module 31: Genetic and Environmental Influences on Intelligence

31-1 What is *heritability*, and what do twin and adoption studies tell us about the nature and nurture of intelligence?

Heritability is the proportion of variation among individuals in a group that can be attributed to genes. Studies of twins, family members, and adoptive parents and siblings indicate a significant hereditary contribution to intelligence scores. Intelligence is polygenic.

31-2 How can environmental influences affect cognitive development?

Studies of children raised in impoverished environments with minimal social interaction indicate that life experiences significantly influence cognitive development. No evidence supports the idea that typical, healthy children can be molded into geniuses by growing up in an exceptionally enriched environment. Environments that foster a *growth mindset* do not alter intelligence, but can positively impact achievement.

31-3 How and why do the genders differ in mental ability scores?

Girls and boys have the same average intelligence test scores, but they tend to differ in some specific abilities. Girls, on average, are better spellers, more verbally fluent, better at reading and at locating objects, better at detecting emotions, and more sensitive to touch, taste, and color. Boys outperform girls at spatial ability and complex mathematics, though boys and girls hardly differ in math computation and overall math performance. Boys also outnumber girls at both the low and high extremes of mental abilities. Evolutionary and cultural explanations have been proposed for these gender differences.

31-4 How and why do racial and ethnic groups differ in mental ability scores?

Racial and ethnic groups differ in their average intelligence test scores. Evidence suggests that environmental differences are responsible for these group differences.

31-5 Are intelligence tests biased or unfair? What is *stereotype threat,* and how does it affect test-takers' performance?

The scientific meaning of bias hinges on a test's ability to predict future behavior for all test-takers, not just for some. In this sense, most experts consider the major U.S. aptitude tests unbiased. However, if we consider bias to mean that a test may be influenced by the test-taker's education and cultural experiences, then intelligence tests, by that definition, may be considered unfair. *Stereotype threat,* a self-confirming concern that we will be evaluated based on a negative stereotype, affects performance on all kinds of tests. Some research findings suggest effective strategies for reducing stereotype threat.

Chapter 11 What Drives Us: Hunger, Sex, Belongingness, and Achievement (Modules 32–35)

Module 32: Basic Motivational Concepts

32-1 How do psychologists define *motivation?* What are four key motivation theories?

Motivation is a need or desire that energizes and directs behavior. The *instinct*/evolutionary perspective explores genetic influences on complex behaviors. *Drive-reduction theory* explores how *physiological needs* create aroused, motivated states (drives) that direct us to satisfy those needs. Environmental *incentives* can intensify drives. Drive-reduction's goal is *homeostasis,* maintaining a steady internal state. Arousal theory proposes that some behaviors (such as those driven by curiosity) do not reduce physiological needs but rather are prompted by a search for an optimal level of arousal. The *Yerkes-Dodson law* describes the relationship between arousal and performance. Abraham Maslow's *hierarchy of needs* proposes a pyramid of human needs, from basic needs up to higher-level needs.

Module 33: Hunger

33-1 What physiological factors produce hunger?

Hunger pangs correspond to stomach contractions, but hunger also has other causes. Neural areas in the brain, some within the hippocampus and hypothalamus, monitor blood chemistry (including level of *glucose*) and incoming information about the body's state. Appetite hormones include ghrelin (secreted by an empty stomach), orexin (secreted by the hypothalamus), leptin (secreted by fat cells), and PYY (secreted by the digestive tract). *Basal metabolic rate* is the body's resting rate of energy expenditure. The body may have a *set point* (a biologically fixed tendency to maintain a given weight) or a looser settling point (also influenced by the environment).

33-2 What cultural and situational factors influence hunger?

Hunger reflects our memory of when we last ate and our expectation of when we should eat again. Humans as a species prefer certain tastes (such as sweet and salty), but our individual preferences are also influenced by conditioning, culture, and situation. Some taste preferences have survival value. Situational influences include the presence of others, serving size, the variety of foods offered, and the way food is presented.

33-3 How does obesity affect physical and psychological health? What factors are involved in weight management?

Obesity, defined by a body mass index (BMI) of 30 or above, is associated with increased depression (especially among women) and bullying, and with many physical health risks. Genes and environment interact to produce obesity. Storing fat was adaptive to our ancestors, and fat requires less food intake to maintain than it did to gain. Set point and metabolism matter. Twin and adoption studies indicate that body weight is also genetically influenced. Environmental influences include sleep loss, social influence, and food and activity levels. Those seeking healthier eating habits are advised to adopt a healthy attitude; exercise and get enough sleep; minimize exposure to unhealthy food cues; limit variety and eat healthy foods; reduce and relabel portions; time your intake to avoid nighttime eating and eat heavier meals earlier in the day; monitor your moods; eat unhurriedly; plan ahead before eating with others; allow for an occasional treat; chart and share your progress; and connect to a support group.

Module 34: Sexual Motivation

34-1 How do hormones influence human sexual motivation?

Our *sexuality* consists of feelings and behaviors that reflect both physiological and psychological influences. For all but those of us who are *asexual*, dating and mating often become a high priority from puberty on. The primary female sex hormones (the estrogens, such as estradiol) and male sex hormone (testosterone) influence human sexual behavior less directly than they influence sexual

behavior in other species. More than other female mammals, however, women's sexuality is responsive to their testosterone level. Testosterone level also varies in men, partly in response to stimulation.

34-2 What is the human *sexual response cycle*, and how do sexual dysfunctions and paraphilias differ?

William Masters and Virginia Johnson described four stages in the human *sexual response cycle:* excitement, plateau, orgasm, and resolution. During resolution there is a *refractory period* (briefer for women) in which renewed arousal and orgasm are impossible. *Sexual dysfunctions* are problems that consistently impair sexual arousal or functioning. They include *erectile disorder* and *female orgasmic disorder*, and can often be successfully treated by behaviorally oriented therapy or drug therapy. *Paraphilias* are considered disordered if a person experiences distress from an unusual sexual interest or if it entails harm or risk of harm.

34-3 How can sexually transmitted infections be prevented?

Safe-sex practices help prevent sexually transmitted infections (STIs). Condoms are especially effective in preventing transmission of HIV, the virus that causes *AIDS.* Knowing one's STI status, and telling one's sexual partner, is an important first step in STI prevention.

34-4 How do external and imagined stimuli contribute to sexual arousal?

External stimuli can trigger sexual arousal. Sexually explicit material may diminish relationship satisfaction, and extensive online pornography exposure may warp expectations and desensitize young adults to normal sexuality. Viewing sexually coercive material can lead to increased acceptance of violence toward women. Imagined stimuli (dreams and fantasies) also influence sexual arousal.

34-5 What factors influence teenagers' sexual behaviors and use of contraceptives?

Teen sexuality varies from culture to culture and era to era. Factors contributing to these variations include communication about sex and contraception, impulsivity, alcohol use, and mass media. High intelligence, religious engagement, father presence, comprehensive sex education, and service-learning participation predict teen sexual restraint.

34-6 What do we know about sexual orientation?

Sexual orientation is the direction of our sexual attraction, as reflected in our longings and fantasies. We may have sexual attraction that is female-male (heterosexual orientation), to our own sex (same-sex orientation), to males and females (bisexual orientation), or to no one at all (asexual orientation). Attitudes

toward same-sex attractions vary across cultures and over time. Regardless of whether a culture condemns or accepts same-sex unions, heterosexuality is most common, but same-sex attraction and other variations exist. The number of people who self-report as gay or bisexual has increased with increased social acceptance. Scientists have been unable to find specific environmental influences that contribute to sexual orientation. Evidence for biological influences includes same-sex attraction in other species, gay-straight trait and brain differences, genetic influences, and prenatal influences.

34-7 What role do social factors play in our sexuality?

Scientific research on sexual motivation does not attempt to define the personal meaning of sex in our lives, which is influenced by many social factors. Sex is a socially significant act. Sexual desire motivates people to form intimate, committed relationships, which in turn enable satisfying sex; sexual desire and love feed each other. Sex at its human best is life uniting and love renewing.

Module 35: Affiliation and Achievement

35-1 What evidence points to our human affiliation need — our need to belong?

Our *affiliation need*—to feel connected and identified with others—had survival value for our ancestors, which may explain why

humans in every society live in groups. According *to self-determination theory*, we strive to satisfy our needs for competence, autonomy, and relatedness. Social bonds help us to be healthier and happier, and feeling loved activates brain regions associated with reward and safety systems. *Ostracism* is the deliberate social exclusion of individuals or groups. Social isolation can put us at risk mentally and physically.

35-2 How does social networking influence us?

We connect with others through social networking, strengthening our relationships, meeting new friends or romantic partners, and finding support at difficult times. But increased online time displaces other activities, and social media leads people to compare their lives with others. Researchers are investigating possible connections between increasing screen time and a rise in teen mental health problems. When networking, people tend toward increased self-disclosure. People with high *narcissism* are especially active on social networking sites. Working out strategies for self-control and disciplined usage can help people maintain a healthy balance between their real-world and online time.

35-3 What is *achievement motivation*, and what are some ways to encourage achievement?

Achievement motivation is a desire for significant accomplishment, for mastery of skills or ideas, for control, and for attaining a high standard. High achievement motivation leads to greater success,

especially when combined with determined, persistent *grit.* Research shows that excessive rewards (driving *extrinsic motivation*) can undermine *intrinsic motivation.* To achieve our own goals, we can make a resolution; announce the goal; develop an implementation plan; create short-term rewards; monitor and record progress; create a supportive environment; and transform the behavior into a habit.

Chapter 12 Emotions, Stress, and Health (Modules 36–40)

Module 36: Introduction to Emotion

36-1 How do arousal, expressive behavior, and cognition interact in emotion?

Emotions are responses of the whole organism, involving bodily arousal, expressive behaviors, and conscious experience resulting from one's interpretations. Theories of emotion generally address two major questions: (1) Does physiological arousal come before or after emotional feelings? And (2) How do feeling and cognition interact? The *James-Lange theory* maintains that emotion occurs when we become aware of our body's response to emotion-inducing stimuli (we observe our heart pounding and feel fear). The *Cannon-Bard theory* proposes that our physiological response to an emotion-inducing stimulus occurs at the same time as our subjective experience of the emotion (one does not cause the other).

36-2 To experience emotions, must we consciously interpret and label them?

The Schachter-Singer *two-factor theory* holds that our emotions have two ingredients: physical arousal and a cognitive label. The cognitive labels we put on our states of arousal are an essential

ingredient of emotion. But Zajonc and LeDoux have contended that some simple emotional responses occur instantly, not only outside our conscious awareness, but before any cognitive processing occurs. This interplay between emotion and cognition illustrates our two-track mind. Lazarus agreed that some emotional responses do not require conscious thinking, but he asserted that appraisals can occur outside of conscious awareness and give rise to emotions.

36-3 What is the link between emotional arousal and the autonomic nervous system?

The arousal component of emotion is regulated by the autonomic nervous system's sympathetic (arousing) and parasympathetic (calming) divisions. In a crisis, the fight-or-flight response automatically mobilizes your body for action.

36-4 How do emotions activate different physiological and brain-pattern responses?

The large-scale body changes that accompany fear, anger, and sexual arousal are very similar (increased perspiration, breathing, and heart rate), though they feel different. Emotions may be similarly arousing, but some subtle physiological responses (such as facial muscle movements) distinguish them. More meaningful differences have been found in activity in some brain pathways and cortical areas.

36-5 How effective are polygraphs in using body states to detect lies?

Polygraphs (machines used in attempts to detect lies) measure several emotion-linked physiological changes, but are not accurate enough to justify widespread use in business and law enforcement. Using the Concealed Information Test may produce better indications of lying.

Module 37: Expressing Emotion

37-1 How do we communicate emotions nonverbally?

Much of our communication is through body movements, facial expressions, and vocal tones. Even seconds-long filmed slices of behavior can reveal feelings.

37-2 How do men and women differ in nonverbal communication?

Women tend to read emotional cues more easily and to be more empathic. They also show greater emotional responsiveness and expressiveness, especially for positive emotions.

37-3 How are gestures and facial expressions understood within and across cultures?

The meaning of gestures and some facial expressions varies by culture, but happy facial expressions are similarly understood all over the world. Context and culture can influence the interpretation

of facial expressions; cultural display rules also influence when we express emotions, which emotions we express, and the amount of emotion expressed.

37-4 How do our external facial expressions influence our internal feelings?

Research on the *facial feedback effect* shows that our facial expressions can trigger emotional feelings and signal our body to respond accordingly. We also mimic others' expressions, which helps us empathize. A similar *behavior feedback effect* is the tendency of behavior to influence our own and others' thoughts, feelings, and actions.

Module 38: Experiencing Emotion

38-1 What are some of the basic emotions?

Most emotion scientists agree that anger, fear, disgust, sadness, and happiness are basic human emotions. Carroll Izard's 10 basic emotions are joy, interest-excitement, surprise, sadness, anger, disgust, contempt, fear, shame, and guilt. Other researchers have identified as many as 28 emotions. Emotions are categorized along two dimensions: valence (positive versus negative) and arousal (low versus high).

38-2 What are the causes and consequences of anger?

Facing a threat or a challenge may trigger anger, and chronic hostility is linked to heart disease. Our culture can influence how we express anger. Emotional venting may be temporarily calming, but it does not reduce anger; expressing anger can make us angrier. Experts suggest reducing the level of physiological arousal of anger by waiting, finding a healthy distraction or support, and trying to move away from the situation mentally. Controlled assertions of feelings may resolve conflicts, and expressing grievances in ways that promote reconciliation can benefit a relationship.

38-3 What is happiness? Why does happiness matter?

Happiness means we have more positive feelings than negative feelings. Happy people tend to be healthy, energized, and have higher levels of *subjective well-being* (satisfaction with life). They also are more willing to help others (the *feel-good, do-good phenomenon*).

38-4 How do time, wealth, adaptation, and comparison affect our happiness levels?

With time, our positive and negative emotions tend to balance out—even over the course of the day. Even significantly bad events are usually not permanently depressing. Having enough money to assure comfort, security, and a sense of control predicts happiness; having more than enough does not increase it. Economic growth in many countries has produced rising inequality, which predicts unhappiness; in countries and states with greater inequality, people with lower incomes experience more ill health, social problems, and

mental disorders. Happiness is relative to our own experiences (the *adaptation-level phenomenon*) and to others' success (the *relative deprivation* principle).

38-5 What predicts happiness, and how can we be happier?

Some people, because of their genetic predispositions and personal histories, are happier than others. Cultures, which vary in the traits they value and the behaviors they expect and reward, also influence personal levels of happiness. Tips for increasing happiness levels: Take charge of your schedule, label your feelings, seek meaningful work and leisure, buy shared experiences rather than things, exercise, sleep enough, foster friendships, find meaning beyond the self, challenge negative thinking, take time to express and record your gratitude, nurture your spirituality, and take an "awe walk."

Module 39: Stress and Illness

39-1 How does our appraisal of an event affect our stress reaction, and what are the three main types of stressors?

Stress is the process by which we perceive and respond to stressors that we appraise as challenging or threatening. If we appraise an event as challenging, we will be aroused and focused in preparation for success; if we appraise it as a threat, we will experience a stress reaction, and our health may suffer. The three main types of stressors are catastrophes; significant life changes; and daily hassles, which include social stress. Daily hassles and social stress

may include inequality and prejudice, chronic workplace stress (which may lead to worker "burnout"), and the conflicts we face between our different *approach and avoidance motives.*

39-2 How do we respond and adapt to stress?

Walter Cannon viewed the stress response as a fight-or-flight system. Hans Selye proposed a general three-phase (alarm, resistance, exhaustion*) general adaptation syndrome (GAS).* People may react to stress by withdrawing. Others, especially women, may have a *tend-and-befriend* response.

39-3 How does stress make us more vulnerable to disease?

Psychoneuroimmunology is the study of how psychological, neural, and endocrine processes together affect our immune system and resulting health. Along with other factors such as age, nutrition, and genetics, stress can prompt the immune system either to overreact (causing an allergic reaction or autoimmune disease) or underreact (allowing an infection to flare or cancer cells to multiply). Stress diverts energy from the immune system, inhibiting the activities of its B and T lymphocytes, macrophages, and NK cells. Stress does not cause illness, but by altering our immune functioning it may make us more vulnerable to diseases and influence their progression.

39-4 Why are some of us more prone than others to coronary heart disease?

Coronary heart disease has been linked with the reactive, anger-prone *Type A* personality. Compared with relaxed, easygoing *Type B* personalities, Type A people's more active sympathetic nervous system may divert blood flow from the liver to the muscles, leaving excess cholesterol and fat circulating in the bloodstream for eventual deposit around the heart. Chronic stress also contributes to persistent inflammation, which is associated with heart and other health problems, including depression.

39-5 So, does stress *cause* illness?

Stress may not directly cause illness, but it does make us more vulnerable, by influencing our physiology and our behaviors.

Module 40: Health and Coping

40-1 In what two ways do people try to alleviate stress?

We use *problem-focused coping* to change the stressor or the way we interact with it. We use *emotion-focused coping* to avoid or ignore stressors and attend to emotional needs related to stress reactions.

40-2 How does a perceived lack of control affect health?

A perceived lack of *personal control* provokes a rise in stress hormones and blood pressure and a lowered immune response, which puts people's health at risk. Being unable to avoid repeated aversive events can lead to *learned helplessness.* Poverty entails less

control, which helps explain the link between economic status and longevity. People who perceive an *internal locus of control* achieve more, enjoy better health, and are happier than those who perceive an *external locus of control.* Belief in free will is linked to more helpful behavior, better learning, and superior persistence, performance, and satisfaction at work.

40-3 Why is self-control important, and can our self-control be depleted?

Self-control requires attention and energy, but predicts good health, higher income, and better school performance; it does better than an intelligence test score in predicting future academic and life success. Self-control tends to weaken after use, recover after rest, and grow stronger when exercised. Researchers disagree about whether self-control can be depleted, but strengthening self-control can lead to a healthier, happier, and more successful life.

40-4 How does an optimistic outlook affect health and longevity?

Studies of people with an optimistic outlook show that they are more likely than pessimists to have optimal health, to be successful, and to have a longer life expectancy.

40-5 How does controlling our feelings affect our well-being and health?

Emotion regulation refers to how we manage our emotions, including which emotions we allow ourselves to feel, when we feel them, and

how we express those emotions. Strategies for emotion regulation include: changing the situation (situation selection); changing how you think about a situation (cognitive reappraisal); and hiding or dampening your emotional expression (suppression).

40-6 How does social support promote good health?

Social support promotes health by calming us, improving our sleep, and reducing blood pressure, and it fosters stronger immune functioning. We can significantly reduce our stress and increase our health by building and maintaining relationships, and by confiding rather than suppressing painful feelings.

40-7 How effective is aerobic exercise as a way to manage stress and improve well-being?

Aerobic exercise helps fight heart disease, predicts longevity, and, in later life, is associated with better cognitive functioning. It boosts mood by promoting muscle relaxation and sounder sleep, triggering the production of neurotransmitters, fostering neurogenesis, and enhancing self-image. It increases arousal and can reduce or prevent depression and anxiety.

40-8 In what ways might relaxation and meditation influence stress and health?

Relaxation and meditation have been shown to lower stress, improve immune functioning, and lessen anxiety and depression. *Mindfulness meditation* is a reflective practice of attending to current

experiences in a nonjudgmental and accepting manner. Massage also promotes relaxation and reduces depression.

40-9 What is the *faith factor,* and what are some possible explanations for the link between faith and health?

The faith factor is the finding that religiously active people tend to live longer than those who are not religiously active do. Possible explanations may include intervening variables such as the healthy behaviors, social support, or positive emotions often found among people who regularly attend religious services.

Chapter 13 Social Psychology (Modules 41–44)

Module 41: Social Thinking

41-1 What do social psychologists study? How do we tend to explain others' behavior and our own?

Social psychologists use scientific methods to study how people think about, influence, and relate to one another. They study the social influences that explain why the same person will act differently in different situations. When explaining others' behavior, we may—especially if we come from an individualist Western culture—commit the *fundamental attribution error,* by underestimating the influence of the situation and overestimating the effects of stable, enduring traits. When explaining our own behavior, we more readily attribute it to the influence of the situation.

41-2 How do attitudes and actions interact?

Our *attitudes* and our actions influence one another. When other influences are minimal, attitudes that are stable, specific, and easily recalled can affect our actions. Actions can modify attitudes, as in the *foot-in-the-door phenomenon* and *role* playing. When our attitudes don't fit with our actions, *cognitive dissonance theory* suggests that we will reduce tension by changing our attitudes to match our actions.

41-3 How do *peripheral route persuasion* and *central route persuasion* differ?

Peripheral route persuasion uses attention-getting cues (such as celebrity endorsement) to trigger fast but relatively thoughtless judgments. *Central route persuasion* offers evidence and arguments to trigger thoughtful responses.

41-4 How can we share our views more effectively?

To persuade people with views that differ from your own, avoid yelling at, humiliating, or boring them with complicated or forgettable information. Instead, identify shared goals and relate your aim to their motives. It also helps to make your message vivid, to repeat it, and to engage others in restating it.

Module 42: Social Influence

42-1 How is social contagion a form of conformity, and how do conformity experiments reveal the power of social influence?

Social contagion (the chameleon effect)—our tendency to unconsciously imitate others' behavior, expressions, postures, voice tones, and moods—is a form of *conformity*. Social networks serve as contagious pathways for moods, both good and bad. Solomon Asch and others found that we are most likely to adjust our behavior or thinking to coincide with a group standard when we feel incompetent or insecure, our group has at least three people,

everyone else agrees, we admire the group's status and attractiveness, we have not already committed to another response, we know we are being observed, and our culture encourages respect for social standards. We may conform to gain approval *(normative social influence)* or because we are willing to accept others' opinions as new information *(informational social influence).*

42-2 What did Milgram's obedience experiments teach us about the power of social influence?

Stanley Milgram's experiments—in which people obeyed orders even when they thought they were harming another person—demonstrated that strong social influences can make ordinary people conform to falsehoods or capitulate to cruelty. Obedience was highest when the person giving orders was nearby and was perceived as a legitimate authority figure, the research was supported by a prestigious institution, the victim was depersonalized or at a distance, and there were no role models for defiance.

42-3 What do the social influence studies teach us about ourselves? How much power do we have as individuals?

These experiments have demonstrated that strong social influences can influence behavior. The power of the individual (personal control) and the power of the situation (social control) interact. Minority influence can also be powerful: A small minority that

consistently expresses its views may sway the majority, as may even a single committed individual.

42-4 How does the presence of others influence our actions, via social facilitation, social loafing, and deindividuation?

In *social facilitation,* the mere presence of others arouses us, improving our performance on easy or well-learned tasks but decreasing it on difficult ones. In *social loafing,* group work makes us feel less responsible, and we may free ride on others' efforts. When the presence of others both arouses us and makes us feel anonymous, we may experience *deindividuation*—loss of self-awareness and self-restraint.

42-5 How can group interaction enable group polarization?

In *group polarization,* group discussions with like-minded others strengthen members' prevailing beliefs and attitudes.

42-6 What role does the internet play in group polarization?

Internet communication magnifies the effect of connecting like-minded people, for better and for worse. People find support, which strengthens their ideas, but also often isolation from those with different opinions. Separation plus conversation may thus lead to group polarization.

42-7 How can group interaction enable groupthink?

Groupthink is driven by a desire for harmony within a decision-making group, overriding realistic appraisal of alternatives. Group leaders can harness the benefits of group interaction by assigning people to identify possible problems, and by welcoming various opinions and expert critique. Small but diverse groups, with varied backgrounds and perspectives, can enable superior outcomes.

Module 43: Antisocial Relations

43-1 What is *prejudice?* How do explicit and implicit prejudice differ?

Prejudice is an unjustifiable, usually negative attitude toward a group and its members. Prejudice's three components are beliefs (often *stereotypes*), emotions, and predispositions to action (*discrimination*). Prejudice may be explicit (overt), or it may be implicit—an unthinking knee-jerk response operating below conscious awareness. Implicit prejudice can cause discrimination even when people do not consciously intend to discriminate.

43-2 What groups tend to experience prejudice?

Prejudice involves explicit and implicit negative attitudes toward people of a particular racial or ethnic group, gender, or sexual orientation. In the United States, frequently targeted groups include Black Americans, women, and LGBTQ people.

43-3 What are some social, emotional, and cognitive roots of prejudice, and what are some ways to reduce prejudice?

The social roots of prejudice include social inequalities and divisions. Higher-status groups often justify their privileged position with the *just-world phenomenon.* We tend to favor our own group (*ingroup bias*) as we divide ourselves into "us" (the *ingroup*) and "them" (the *outgroup*). Prejudice can also be a tool for protecting our emotional well-being, as when we focus our anger by blaming events on a *scapegoat.* The cognitive roots of prejudice grow from our natural ways of processing information: forming categories, remembering vivid cases, and believing that the world is just (and that our own and our group's ways of doing things are the right ways). Monitoring our feelings and actions, as well as developing new friendships, can help us free ourselves from prejudice.

43-4 How does psychology's definition of *aggression* differ from everyday usage? What biological factors make us more prone to hurt one another?

In psychology's more specific meaning, *aggression* is any physical or verbal behavior intended to harm someone physically or emotionally. Biology influences our threshold for aggressive behaviors at three levels: genetic (inherited traits), neural (activity in key brain areas), and biochemical (such as alcohol or excess testosterone in the bloodstream). Aggression is a complex behavior resulting from the interaction of biology and experience.

43-5 What psychological and social-cultural factors may trigger aggressive behavior?

Frustration (the *frustration-aggression principle*), previous reinforcement for aggressive behavior, and observing aggressive role models all contribute to aggression. Media violence provides *social scripts* that children learn to follow. Viewing sexual violence contributes to greater aggression toward women. Playing violent video games can increase aggressive thoughts, emotions, and behaviors.

Module 44: Prosocial Relations

44-1 Why do we befriend or fall in love with some people but not others?

Proximity (geographical nearness) increases liking, in part because of the *mere exposure effect*—exposure to novel stimuli increases liking of those stimuli. Physical attractiveness increases social opportunities and improves the way we are perceived. Similarity of attitudes and interests greatly increases liking, especially as relationships develop. We also like those who like us.

44-2 How does romantic love typically change as time passes?

Intimate love relationships start with *passionate love*—an intensely aroused state. Over time, the strong affection of *companionate love*

may develop, especially if enhanced by an *equitable* relationship, intimate *self-disclosure,* and positive support.

44-3 What is *altruism?* When are people most — and least — likely to help?

Altruism is unselfish regard for the well-being of others. We are most likely to help when we notice an incident, interpret it as an emergency, and assume responsibility for helping. Other factors, including our mood and our similarity to the victim, also affect our willingness to help. We are least likely to help if other bystanders are present (the *bystander effect*).

44-4 How do social exchange theory and social norms explain helping behavior?

Social exchange theory is the view that we help others because it is in our own self-interest; in this view, the goal of social behavior is maximizing personal benefits and minimizing costs. Others believe that helping results from socialization, in which we are taught guidelines for expected behaviors in social situations, such as the *reciprocity norm* and the *social-responsibility norm.*

44-5 How do social traps and mirror-image perceptions fuel social conflict?

Social traps are situations in which people in *conflict* pursue their own individual self-interest, harming the collective well-being.

Individuals and cultures in conflict also tend to form *mirror-image perceptions:* Each party views itself as an ethical, peaceful victim, and the opponent as untrustworthy and evil-intentioned. Perceptions can become *self-fulfilling prophecies.*

44-6 What can we do to promote peace?

Peace can result when individuals or groups work together to achieve *superordinate* (shared) *goals.* Research indicates that contact, cooperation, communication, and conciliation—such as the Graduated and Reciprocated Initiatives in Tension-Reduction (*GRIT*) strategy—help promote peace.

Chapter 14 Personality (Modules 45–47)

Module 45: Introduction to Personality and Psychodynamic Theories

45-1 What is *personality*, and what theories inform our understanding of personality?

Personality is an individual's characteristic pattern of thinking, feeling, and acting. Psychoanalytic (and later psychodynamic) theory and humanistic theory have become part of Western culture. They also laid the foundation for later theories, such as trait and social-cognitive theories of personality.

45-2 How did Freud's treatment of psychological disorders lead to his view of the unconscious mind?

Psychodynamic theories of personality view behavior as a dynamic interaction between the conscious and unconscious mind. These theories trace their origin to Sigmund Freud's theory of *psychoanalysis.* In treating patients whose disorders had no clear physical explanation, Freud concluded that these problems reflected unacceptable thoughts and feelings, hidden away in the *unconscious*

mind. To explore this hidden part of a patient's mind, Freud used *free association* and dream analysis.

45-3 What was Freud's view of personality?

Freud believed that personality results from conflict arising from the interaction among the mind's three systems: the *id* (pleasure-seeking impulses), *ego* (reality-oriented executive), and *superego* (internalized set of ideals, or conscience).

45-4 What developmental stages did Freud propose?

He believed children pass through five *psychosexual stages* (oral, anal, phallic, latency, and genital). He proposed that boys develop the *Oedipus complex* during the phallic stage, but then gradually incorporate their father's values into their superegos in a process called *identification.* According to this view, unresolved conflicts at any stage can leave a person's pleasure-seeking impulses *fixated* (stalled) at that stage.

45-5 How did Freud think people defended themselves against anxiety?

For Freud, anxiety was the product of tensions between the demands of the id and superego. The ego copes by using unconscious *defense mechanisms,* such as *repression,* which he viewed as the basic mechanism underlying and enabling all the others.

45-6 Which of Freud's ideas did his followers accept or reject?

Freud's early followers, the neo-Freudians, accepted many of his ideas. They differed in placing more emphasis on the conscious mind and in stressing social motives more than sex or aggression. Most contemporary psychodynamic theorists and therapists reject Freud's emphasis on sexual motivation. They stress, with support from modern research findings, that much of our mental life is unconscious, and they believe that our childhood experiences influence our adult personality and attachment patterns. Many also believe that our species' shared evolutionary history shaped some universal predispositions.

45-7 How do contemporary psychologists view Freud's psychoanalysis?

Freud is credited with drawing attention to the unconscious and the irrational, the importance of human sexuality and the conflict between biological impulses and social restraints, and for formulating some science-backed defense mechanisms. But his concept of repression, and his view of the unconscious as a collection of repressed and unacceptable thoughts, wishes, feelings, and memories, cannot survive scientific scrutiny. Freud offered after-the-fact explanations, which are hard to test scientifically. Research does not support many of Freud's specific ideas, such as the view that development (which we now know is lifelong) is fixed in childhood.

45-8 How has modern research developed our understanding of the unconscious?

Research confirms that we do not have full access to all that goes on in our mind, though today's science views the unconscious as a separate and parallel track of information processing that occurs outside our awareness. This processing includes schemas that control our perceptions, priming, implicit memories of learned skills, instantly activated emotions, and the implicit prejudice and stereotypes that filter our information processing of others' traits and characteristics. Research also supports reaction formation and projection (the false consensus effect), and the idea that we unconsciously defend ourselves from anxiety (as seen in experiments testing *terror-management theory*).

45-9 What are *projective tests,* how are they used, and what are some criticisms of them?

Projective tests show people stimuli that are open to many possible interpretations, treating their answers as revelations of inner dynamics. The *Thematic Apperception Test (TAT)* and the *Rorschach inkblot test* are two such tests. The TAT provides a valid and reliable map of people's implicit motives that is consistent over time. The Rorschach has low reliability and validity, but some clinicians value it as a source of suggestive leads, an icebreaker, or a revealing interview technique.

Module 46: Humanistic Theories and

Trait Theories

46-1 How did humanistic psychologists view personality, and what was their goal in studying personality?

The *humanistic* psychologists' view of personality focused on the potential for healthy personal growth and people's striving for self-determination and self-realization. Abraham Maslow proposed that human motivations form a *hierarchy of needs;* if basic needs are fulfilled, people will strive toward *self-actualization* and *self-transcendence.* Carl Rogers believed that the ingredients of a growth-promoting environment are acceptance (including *unconditional positive regard*), genuineness, and empathy. *Self-concept* was a central feature of personality for both Maslow and Rogers.

46-2 How did humanistic psychologists assess a person's sense of self?

Some rejected any standardized assessments and relied on interviews and conversations. Others, like Rogers, sometimes used questionnaires in which people described their ideal and actual selves; these were later used to judge progress during therapy. Some now use the life story approach, enabling a rich narrative detailing each person's unique life history.

46-3 How have humanistic theories influenced psychology? What criticisms have they faced?

Humanistic psychology has had pervasive cultural impact; it also laid the groundwork for today's scientific subfield of positive psychology. Critics have said that humanistic psychology's concepts are vague and subjective, its values self-centered, and its assumptions naively optimistic.

46-4 How do psychologists use traits to describe personality?

Trait theorists see personality as a stable and enduring pattern of behavior. They have been more interested in trying to describe our differences than in explaining them. Using factor analysis, they identify clusters of behavior tendencies that occur together. Genetic predispositions influence many traits.

46-5 What are some common misunderstandings about introversion?

Western cultures prize extraversion, but introverts have different, equally important skills. Introversion does not equal shyness, and introverted leaders outperform extraverts in some contexts. Introverts handle conflict well, seeking solitude rather than revenge.

46-6 What are *personality inventories,* and what are their strengths and weaknesses as trait-assessment tools?

Personality inventories (such as the *MMPI*) are questionnaires on which people respond (*self-report)* to items designed to gauge a wide range of feelings and behaviors. Test items are *empirically derived,*

and the tests are objectively scored. Objectivity does not guarantee validity; people can fake their answers to create a good impression (but may then score high on a lie scale that assesses faking).

46-7 Which traits seem to provide the most useful information about personality variation?

The *Big Five* personality factors—openness, conscientiousness, extraversion, agreeableness, and neuroticism (OCEAN)—currently offer our best approximation of the basic trait dimensions. These factors are generally stable and describe people in various cultures reasonably well. Many genes, each having small effects, combine to influence our traits.

46-8 Does research support the consistency of personality traits over time and across situations?

A person's average traits persist over time and are predictable over many different situations. But traits cannot predict behavior in any one situation.

Module 47: Social-Cognitive Theories and the Self

47-1 How do social-cognitive theorists view personality development, and how do they explore behavior?

Albert Bandura's *social-cognitive perspective* emphasizes the interaction of our traits with our situations. Social-cognitive researchers apply principles of learning, cognition, and social behavior to personality. *Reciprocal determinism* describes the interaction and mutual influence of behavior, internal cognition, and environment. Assessment situations involving simulated conditions exploit the principle that the best predictor of future behavior is a person's actions in similar situations.

47-2 What criticisms have social-cognitive theories faced?

Social-cognitive theories build on well-established concepts of learning and cognition, sensitizing researchers to the ways situations affect, and are affected by, individuals. They have been faulted for underemphasizing the importance of unconscious motives, emotions, and biologically influenced traits.

47-3 Why has psychology generated so much research on the self?

The *self* is vigorously researched as the center of personality, organizing our thoughts, feelings, and actions. Considering possible selves helps motivate us toward positive development, but focusing too intensely on ourselves can lead to the *spotlight effect.*

47-4 How important is self-esteem to our well-being?

High *self-esteem* and *self-efficacy* correlate with benefits such as higher school achievement and with being able to meet challenges.

But the direction of the correlation is unclear. Rather than unrealistically promoting self-worth, it's better to reward achievements, thus promoting feelings of competence.

47-5 How do excessive optimism, blindness to one's own incompetence, and self-serving bias reveal the costs of self-esteem, and how do defensive and secure self-esteem differ?

Excessive optimism can lead to complacency and prevent us from seeing real risks, while blindness to one's own incompetence may lead us to make the same mistakes repeatedly. People are often most overconfident when they are most incompetent, a phenomenon known as the Dunning-Kruger effect. Asking others for a candid assessment can help us to counter the self-serving bias that would otherwise lead us to overestimate our own skills. *Self-serving bias* is our tendency to perceive ourselves favorably, as when viewing ourselves as better than average or when accepting credit for our successes but not blame for our failures. Excessive self-love leads to *narcissism.* Defensive self-esteem is fragile, focuses on sustaining itself, and views failure or criticism as a threat. Secure self-esteem enables us to feel accepted for who we are.

Chapter 15 Psychological Disorders (Modules 48–53)

Module 48: Introduction to Psychological Disorders

48-1 How should we draw the line between typical behavior and a disorder?

According to psychologists and psychiatrists, *psychological disorders* are marked by a clinically significant disturbance in an individual's cognition, emotion regulation, or behavior. Such dysfunctional or maladaptive thoughts, emotions, or behaviors—which are often accompanied by distress—interfere with daily life, and thus are disordered.

48-2 How do the medical model and the biopsychosocial approach influence our understanding of psychological disorders?

The *medical model* assumes that psychological disorders have physical causes that can be diagnosed, treated, and often cured through therapy, sometimes in a hospital. The biopsychosocial perspective assumes that disordered behavior comes from the interaction of biological characteristics, psychological dynamics, and social-cultural circumstances. This approach has given rise to the vulnerability-stress model, in which individual characteristics

and environmental stressors combine to increase or decrease the likelihood of developing a psychological disorder, a model supported by *epigenetics* research.

48-3 How and why do clinicians classify psychological disorders, and why do some psychologists criticize diagnostic labels?

The American Psychiatric Association's DSM-5-TR (*Diagnostic and Statistical Manual of Mental Disorders,* Fifth Edition, Text Revision) contains diagnostic labels and descriptions that provide a common language and shared concepts for communication and research. Critics of the DSM say it casts too wide a net, pathologizing typical behaviors. A complementary approach to classification is the U.S. National Institute of Mental Health's Research Domain Criteria (RDoC) project, a framework that organizes disorders according to behaviors and brain activity along several dimensions. The Hierarchical Taxonomy of Psychopathology (HiTOP) is another approach that emphasizes the different numbers of people's symptoms and the connections between disorders. Any classification attempt produces diagnostic labels that may create preconceptions, which bias perceptions of the labeled person's past and present behavior.

48-4 What factors increase the risk of suicide, and what do we know about nonsuicidal self-injury?

Suicide rates differ by nation, race, gender, age group, income, religious involvement, marital status, and other factors. In most

countries, suicide rates have been decreasing, but in the United States and Canada they have been increasing. Those lacking social support, such as many gay, transgender, and gender nonconforming youth, are at increased risk, as are people who have been anxious or depressed. Isolation and unemployment can also heighten risk. Forewarnings of suicide may include verbal hints, giving away possessions, social withdrawal, and preoccupation with death. People who talk about suicide should be taken seriously: Listen and empathize, connect them to help, and protect those who appear at immediate risk. Nonsuicidal self-injury (NSSI) does not usually lead to suicide but may escalate to suicidal thoughts and acts if untreated. People who engage in NSSI do not tolerate stress well and tend to be self-critical and impulsive.

48-5 Do psychological disorders predict violent behavior?

Mental disorders seldom lead to violence, and clinicians cannot predict who is likely to harm others. Most people with disorders are nonviolent and are more likely to be victims than attackers. Better predictors of violence are alcohol or drug use, previous violence, gun availability, and brain damage.

48-6 How many people have, or have had, a psychological disorder? What are some of the risk factors?

Psychological disorder rates vary, depending on the time and place of the survey. Poverty is a risk factor. But some disorders, such as schizophrenia, can also drive people into poverty. Immigrants to the

United States may average better mental health than their U.S.-born counterparts with the same ethnic heritage (a phenomenon known as the immigrant paradox).

Module 49: Anxiety Disorders, Obsessive-Compulsive and Related Disorders, Trauma- and Stressor-Related Disorders, and Somatic Symptom and Related Disorders

49-1 How do generalized anxiety disorder, panic disorder, and specific phobias differ?

Anxiety disorders are psychological disorders characterized by distressing, persistent anxiety or maladaptive behaviors that reduce anxiety. People with *generalized anxiety disorder* feel persistently and uncontrollably tense and apprehensive, for no apparent reason. In the more extreme *panic disorder,* anxiety escalates into episodes of intense dread. Those with a *specific phobia* show an intense and irrational fear of a particular object, activity, or situation.

49-2 What is *OCD?*

Persistent and repetitive thoughts (obsessions), actions (compulsions), or both characterize *obsessive-compulsive disorder (OCD).*

49-3 What is *PTSD?*

Symptoms of *posttraumatic stress disorder (PTSD)* include 4 or more weeks of haunting memories, nightmares, hypervigilance, avoidance of trauma-related stimuli, social withdrawal, jumpy anxiety, numbness of feeling, and/or sleep problems following a traumatic event.

49-4 What is a *somatic symptom disorder?*

People who experience bodily symptoms without any apparent physical cause may be experiencing *somatic symptom disorder*. Those with *illness anxiety disorder* (previously known as hypochondriasis) interpret normal physical sensations as symptoms of a disease.

49-5 How do learning, cognition, and biology contribute to the feelings and thoughts that mark anxiety disorders, OCD, PTSD, and somatic symptom disorders?

The learning perspective views these disorders as products of fear conditioning, stimulus generalization, fearful-behavior reinforcement, and observational learning of others' fears and cognitions. The cognitive perspective focuses on the effects of our thoughts, memories, interpretations, and expectations in what we learn to fear. The biological perspective considers genetic predispositions, brain overarousal, and the role that fears of life-threatening dangers played in natural selection and evolution.

Module 50: Depressive Disorders and Bipolar Disorders

50-1 How do depressive disorders and bipolar disorders differ?

Depressive disorders are characterized by an enduring sad, empty, or irritable mood, along with physical and cognitive changes that affect a person's ability to function. A person with *major depressive disorder* experiences at least five symptoms of depression (including either depressed mood or loss of interest or pleasure) for 2 or more weeks. A person with a *bipolar disorder* experiences not only depression but also *mania*—episodes of hyperactive and wildly optimistic, impulsive behavior.

50-2 How can the biological and social-cognitive perspectives help us understand depressive disorders and bipolar disorders?

The biological perspective on depressive disorders and bipolar disorders focuses on genetic predispositions, unusual brain structure and activity (including activity within neurotransmitter systems), and nutritional effects. The social-cognitive perspective views depression as an ongoing cycle of stressful experiences—interpreted through negative beliefs, attributions, and memories, often with relentless *rumination*—leading to negative moods, thoughts, and actions, thereby fueling new stressful experiences.

Module 51: Schizophrenia

51-1 What patterns of perceiving, thinking, and feeling characterize schizophrenia?

Schizophrenia is a *psychotic disorder* characterized by *delusions,* hallucinations, disorganized speech, and/or diminished, inappropriate emotional expression. Hallucinations are sensory experiences without sensory stimulation; delusions are false beliefs. Schizophrenia symptoms may be positive (the presence of inappropriate behaviors) or negative (the absence of appropriate behaviors).

51-2 How do *chronic schizophrenia* and *acute schizophrenia* differ?

Schizophrenia typically strikes during late adolescence or early adulthood, affects slightly more men than women, and occurs in all cultures. In *chronic* (or process) *schizophrenia,* development of symptoms is gradual and recovery is doubtful. In *acute* (or reactive) *schizophrenia,* onset is sudden, in reaction to stress, and prospects for recovery are brighter.

51-3 What brain abnormalities are associated with schizophrenia?

People with schizophrenia have an excess number of dopamine receptors, which may intensify brain signals, creating positive symptoms such as hallucinations and paranoia. Brain scans have revealed abnormal activity in the frontal lobes, thalamus, and

amygdala, as well as a loss of neural connections across the brain network. Brain abnormalities associated with schizophrenia include enlarged, fluid-filled areas and corresponding shrinkage and thinning of cerebral tissue. Smaller-than-normal areas may include the cortex, the hippocampus, the corpus callosum, and the thalamus.

51-4 What prenatal events are associated with increased risk of developing schizophrenia?

Possible contributing factors include maternal diabetes; older paternal age; viral infections, famine conditions, or extreme maternal stress during pregnancy; and low weight or oxygen deprivation at birth.

51-5 How do genes influence schizophrenia? What factors may be early warning signs of schizophrenia in children?

Twin and adoption studies indicate that the predisposition to schizophrenia is inherited. Multiple genes probably interact to produce schizophrenia. No environmental causes invariably produce schizophrenia, but environmental events (such as prenatal viruses or maternal stress) may "turn on" genes in those who are predisposed to this disorder. Possible early warning signs of schizophrenia include social withdrawal; a mother with severe and long-lasting schizophrenia; birth complications; short attention span; poor muscle coordination; emotional unpredictability; poor

peer relations and solo play; separation from parents; and childhood abuse.

Module 52: Dissociative, Personality, and Eating Disorders

52-1 What are *dissociative disorders,* and why are they controversial?

Dissociative disorders are controversial, rare disorders characterized by a disruption of or discontinuity in the normal integration of consciousness, memory, identity, emotion, perception, body representation, motor control, and behavior. Skeptics note that diagnoses of *dissociative identity disorder (DID)* increased dramatically in the late twentieth century, is rarely found outside North America, and may reflect role playing by people vulnerable to therapists' suggestions. Others view DID as a manifestation of feelings of anxiety, or as a response learned when behaviors are reinforced by anxiety reduction.

52-2 What are the three clusters of personality disorders? What behaviors and brain activity characterize antisocial personality disorder?

Personality disorders are characterized by enduring inner experiences or behavior patterns that differ from someone's cultural norms and expectations, are pervasive and inflexible, begin in adolescence or

early adulthood, are stable over time, and cause distress or impairment. The 10 DSM-5-TR disorders tend to form three clusters, characterized by eccentric or odd behaviors (Cluster A); dramatic, emotional, or erratic behaviors (Cluster B); and anxious or fearful behaviors (Cluster C). *Antisocial personality disorder* (one of those in Cluster B) is characterized by a lack of conscience and, sometimes, by aggressive and fearless behavior. The amygdala is smaller, the brain cortex is smaller and thinner, and the frontal lobes are less active in people with this disorder, leading to impaired frontal lobe cognitive functions and decreased responsiveness to others' distress. Genetic predispositions may interact with the environment to produce these characteristics.

52-3 What are the three main eating disorders, and how do biological, psychological, and social-cultural influences make some people more vulnerable to them?

In those with eating disorders, psychological factors overwhelm the body's tendency to maintain a healthy weight. Regardless of their actual weight, people with *anorexia nervosa* (usually adolescent girls) maintain a starvation diet, sometimes exercise excessively, and have an inaccurate self-perception. Those with *bulimia nervosa* binge and then compensate by purging, fasting, or excessively exercising. Bulimia is marked by weight fluctuations within or above typical ranges. Those with *binge-eating disorder* are preoccupied with food and engage in significant bouts of bingeing, but they do not follow binges with purging, fasting, or exercising. Cultural pressures, low

self-esteem, and negative emotions interact with stressful life experiences and genetics to produce eating disorders.

Module 53: Neurodevelopmental Disorders

53-1 What is *intellectual developmental disorder?*

Intellectual developmental disorder is marked by limited mental ability, which is indicated by an intelligence score of 70 or below and difficulty adapting to the demands of life in three skill areas: conceptual, social, and practical.

53-2 What is *autism spectrum disorder?*

Autism spectrum disorder (ASD) is a cognitive and social-emotional disorder that appears in childhood and is marked by limitations in communication and social interaction, as well as rigidly fixated interests and repetitive behaviors.

53-3 Why is there controversy over attention-deficit/hyperactivity disorder*?*

A child (or, less commonly, an adult) who displays extreme inattention and/or hyperactivity and impulsivity may be diagnosed with *attention-deficit/hyperactivity disorder (ADHD).* Controversies center on whether the growing number of ADHD cases reflects

overdiagnosis or increased awareness of the disorder, and on the long-term effects of stimulant-drug treatment.

Chapter 16 Therapy (Modules 54–56)

Module 54: Introduction to Therapy and the Psychological Therapies

54-1 How do *psychotherapy* and the *biomedical therapies* differ?

Psychotherapy is treatment involving psychological techniques that consists of interactions between a trained therapist and someone seeking to overcome psychological difficulties or achieve personal growth. The major psychotherapies derive from psychology's psychodynamic, humanistic, behavioral, and cognitive perspectives, with many psychotherapists taking an *eclectic approach* that blends therapies. *Biomedical therapy* treats psychological disorders with medications or procedures that act directly on a person's physiology.

54-2 What are the goals and techniques of psychoanalysis, and how have they been adapted in psychodynamic therapy?

Through *psychoanalysis,* Sigmund Freud tried to give people self-insight and relief from their disorders by bringing anxiety-laden feelings and thoughts into conscious awareness. Psychoanalytic techniques included using free association and *interpretation* of instances of *resistance* and *transference. Psychodynamic therapy* has

been influenced by traditional psychoanalysis but differs from it in many ways, including little attention to the concepts of id, ego, and superego. This contemporary therapy is briefer, less expensive, and more focused on helping the client find relief from current symptoms. Psychodynamic therapists help clients understand how past relationships create themes that may be acted out in present relationships.

54-3 What are the basic themes of humanistic therapy? What are the goals and techniques of Rogers' person-centered approach?

Both psychodynamic and humanistic therapies are *insight therapies*—they attempt to improve functioning by increasing people's awareness of motives and defenses. Humanistic therapy's goals include helping people grow in self-awareness and self-acceptance; promoting personal growth rather than curing illness; helping people take responsibility for their own growth; focusing on conscious thoughts rather than unconscious motivations; and seeing the present and future as more important than the past. Carl Rogers' *person-centered therapy* proposed that therapists' most important contribution is to function as a psychological mirror through *active listening* and to provide a growth-fostering environment of *unconditional positive regard.*

54-4 How does the basic assumption of behavior therapy differ from the assumptions of psychodynamic and humanistic

therapies? What classical conditioning techniques are used in exposure therapies and aversive conditioning?

Behavior therapies are not insight therapies, and instead assume that problem behaviors *are* the problem. Their goal is to apply learning principles to modify these problem behaviors. Classical conditioning techniques, including *exposure therapies* (such as *systematic desensitization* or *virtual reality exposure therapy*) and *aversive conditioning,* attempt to change behaviors through *counterconditioning*—evoking new responses to old stimuli that trigger unwanted behaviors.

54-5 What is the main premise of behavior therapy based on operant conditioning principles, and what are the views of its proponents and critics?

Operant conditioning operates under the premise that voluntary behaviors are strongly influenced by their consequences. Therapy based on operant conditioning principles therefore uses behavior modification techniques to change unwanted behaviors by positively reinforcing desired behaviors and ignoring or punishing undesirable behaviors. Critics maintain that (1) techniques such as those used in *token economies* may produce behavior changes that disappear when rewards end, and (2) deciding which behaviors should change is authoritarian and unethical. Proponents argue that treatment with positive rewards is more humane than institutionalizing people for undesired behaviors.

54-6 What are the goals and techniques of the cognitive therapies and of cognitive-behavioral therapy?

The *cognitive therapies,* such as Aaron Beck's cognitive therapy for depression, assume that our thinking colors our feelings, and that the therapist's role is to change clients' self-defeating thinking by training them to perceive and interpret events in more constructive ways. The widely researched and practiced *cognitive-behavioral therapy (CBT)* combines cognitive therapy and behavior therapy by helping clients regularly try out their new ways of thinking and behaving in their everyday life. Dialectical behavior therapy (DBT) combines cognitive tactics for tolerating distress and regulating emotions with social skills training and mindfulness meditation. Acceptance and commitment therapy (ACT) helps clients learn to accept their feelings and act in ways that reflect their life values.

54-7 What are the aims and benefits of group therapy, couples therapy, and family therapy?

Group therapy sessions can help more people with less cost than individual therapy. Clients may benefit in person or online from exploring feelings and developing social skills in a group situation, from learning that others have similar problems, and from getting feedback on new ways of behaving. *Couples therapy* focuses on how romantic partners can improve their interactions, which can increase emotional intimacy, healthy communication, and relationship satisfaction. *Family therapy* aims to help family

members discover the roles they play within the family's interactive social system, improve communication, and learn new ways to prevent or resolve conflicts.

Module 55: Evaluating Psychotherapies

55-1 Does psychotherapy work? How can we know?

Clients' and therapists' positive testimonials cannot prove that psychotherapy is effective, and the placebo effect and *confirmation bias* make it difficult to judge whether improvement occurred because of the treatment. Using *meta-analyses* to statistically combine the results of hundreds of randomized psychotherapy outcome studies, researchers have found that those not undergoing treatment often improve, but those undergoing psychotherapy are more likely to improve—and to improve more quickly and with less risk of relapse.

55-2 Are some psychotherapies more effective than others for specific disorders?

No one type of psychotherapy is generally superior to all others. Therapy is most effective for those with clear-cut, specific problems. Some therapies—such as behavior conditioning for treating specific phobias and compulsions—are more effective for particular disorders. Cognitive and cognitive-behavioral therapies have been

effective in coping with anxiety, panic disorder, posttraumatic stress disorder, insomnia, and depression; behavioral conditioning therapies with specific behavior problems; psychodynamic therapy for depression and anxiety; and nondirective (client-centered) counseling for mild to moderate depression. Abnormal states tend to return to normal on their own, and the placebo effect can create the impression that a treatment has been effective. *Evidence-based practice* integrates the best available research with clinicians' expertise and clients' culture, values, personality, identity, and circumstances.

55-3 What three elements are shared by all effective forms of psychotherapy?

All effective psychotherapies offer new hope for demoralized people; a fresh perspective; and (if the therapist is effective) an empathic, trusting, and caring relationship. The emotional bond of trust and understanding between therapist and client—the *therapeutic alliance*—is an important element in effective therapy.

55-4 What personal factors influence the therapist-client relationship?

Therapists differ in the values that influence their goals in therapy and their views of progress. They may also differ from their clients. These differences may create problems if therapists and clients differ in their cultural, religious, or personal values and perspectives.

55-5 When should people seek therapy, and what should they look for when selecting a therapist?

Campus health centers are generally good starting points for counseling options, and they may offer some free services. A person seeking therapy may want to ask about the therapist's treatment approach, values, credentials, and fees. An important consideration is whether the therapy seeker feels comfortable and able to establish a bond with the therapist. Recognizing the importance of a strong therapeutic alliance, the American Psychological Association accredits programs that provide training in cultural sensitivity and that recruit underrepresented cultural groups.

55-6 What ethical principles guide psychotherapy and psychological research on mental illness?

Psychotherapists and psychological researchers on mental health must follow their country's ethical principles and code of conduct, aiming to benefit others, to be honest and truthful, and to never expose people to greater risks than would be encountered in everyday life.

Module 56: The Biomedical Therapies and Preventing Psychological Disorders

56-1 Why is therapeutic lifestyle change considered an effective biomedical therapy, and how does it work?

Therapeutic lifestyle change is considered a biomedical therapy because it influences the way the brain responds. Mind and body are a unit; affect one and you will affect the other. Our exercise, nutrition, relationships, recreation, service to others, relaxation, and religious or spiritual engagement affect our mental health. People who undergo a program of aerobic exercise, adequate sleep, light exposure, social engagement, rumination reduction, and better nutrition have gained relief from depressive symptoms.

56-2 What are the drug therapies? How do double-blind studies help researchers evaluate a drug's effectiveness?

Psychopharmacology has helped make drug therapy the most widely used biomedical therapy. *Antipsychotic drugs* are used in treating schizophrenia; some block dopamine activity. Side effects may include tardive dyskinesia (involuntary movements of facial muscles, tongue, and limbs) or increased risk of obesity and diabetes. *Antianxiety drugs,* which depress central nervous system activity, are used to treat anxiety disorders, obsessive-compulsive disorder, and posttraumatic stress disorder, and can be addictive.

Antidepressant drugs, which often increase the availability of serotonin and norepinephrine, are used to treat depression, anxiety disorders, obsessive-compulsive and related disorders, and posttraumatic stress disorder. Given their use in treating disorders other than depressive ones (from anxiety to strokes), these drugs are more often called SSRIs (selective serotonin reuptake inhibitors) rather than antidepressants. Quicker-acting antidepressants may include ketamine and microdoses of psychedelic drugs such as psilocybin. Lithium and Depakote are mood stabilizers prescribed for those with a bipolar disorder. Studies may use a double-blind procedure to avoid the placebo effect and researcher bias.

56-3 How are brain stimulation and psychosurgery used in treating specific disorders?

Electroconvulsive therapy (ECT), in which a brief electric current is sent through the brain of an anesthetized patient, is an effective treatment for severe depression in people who have not responded to other therapy. Newer alternative treatments for depression include transcranial direct current stimulation (tDCS), *transcranial magnetic stimulation (TMS),* and deep-brain stimulation (DBS; may calm an overactive brain region linked with negative emotions in some patients). *Psychosurgery* removes or destroys brain tissue in hopes of modifying behavior. Radical psychosurgical procedures such as *lobotomy* are no longer performed. Today's microscale psychosurgery and MRI-guided precision brain surgery are rare, last-resort treatments because the effects are irreversible.

56-4 What may help prevent psychological disorders, and why is it important to develop resilience?

Preventive mental health programs are based on the idea that many psychological disorders could be prevented by identifying and alleviating the conditions that cause them, such as poverty, lack of meaningful work, constant criticism, unemployment, and discrimination. Community psychologists work to prevent psychological disorders by turning destructive environments into ones that support psychological health. This includes efforts to build people's *resilience,* helping them cope and recover from stress. Struggling with challenges can lead to *posttraumatic growth*.

Note: There are no learning objective questions in Appendix A, The Story of Psychology: A Timeline; and Appendix B, Career Fields in Psychology.

Appendix C Psychology at Work

Work and Life Satisfaction

C-1 What is *flow?*

Flow is a completely involved, focused state of consciousness with diminished awareness of self and time. It results from fully engaging one's skills. Interests predict both performance and persistence, so

people should aim to find vocations with a strong person-environment fit.

Industrial-Organizational Psychology

C-2 What are industrial-organizational psychology's three key areas of study?

Three key areas of study related to *industrial-organizational (I/O) psychology* are *personnel, organizational,* and *human factors psychology*. Each uses psychological principles to study and benefit the wide range of today's workers, workplaces, and work activities.

Personnel Psychology

C-3 How do personnel psychologists facilitate job seeking, employee selection, work placement, and performance appraisal?

Personnel psychologists work to provide training programs for job seekers, devise selection methods for new employees, recruit and evaluate diverse applicants, design and evaluate training programs, identify people's interests and strengths, analyze job content, appraise individual and organizational performance, and facilitate team building. Unstructured, subjective interviews foster the interviewer illusion; *structured interviews* pinpoint job-relevant strengths and are better predictors of performance. Checklists,

graphic rating scales, and behavior rating scales are useful performance appraisal methods.

Organizational Psychology

C-4 Why are organizational psychologists interested in employee satisfaction and engagement?

Organizational psychologists examine influences on worker satisfaction and productivity and facilitate organizational change. Employee satisfaction and engagement tend to correlate with organizational success; in fact, employee attitudes predict future business success.

C-5 How can leaders be most effective?

Effective leaders set specific, challenging goals and choose an appropriate *leadership style.* Leadership style may be goal-oriented *(task leadership),* group-oriented *(social leadership),* or some combination of the two. Effective management often involves positive reinforcement, fulfilling the need to belong, and participative management.

C-6 What cultural influences need to be considered when choosing an effective leadership style?

Project GLOBE studies cultural variations in leadership expectations. Leaders who fulfill expectations (being directive in some cultures or

participative in others) tend to be successful. But thriving companies worldwide tend to focus on identifying and enhancing employee strengths; strengths-based leadership pays dividends everywhere.

Human Factors Psychology

C-7 How do human factors psychologists work to create user-friendly machines and work settings?

Human factors psychologists contribute to human safety and improved design by encouraging developers and designers to consider human abilities and behaviors, to user-test their work before production and distribution, and to remain mindful of the curse of knowledge.

Appendix E

Answers to the *Retrieval Practice* and *Module Test* Questions

Chapter 1 Thinking Critically With Psychological Science (Modules 1–3)

MODULE 1: The History and Scope of Psychology

Retrieval Practice Answers

RP-1 Examining our own assumptions, appraising the source, discerning hidden biases, and assessing conclusions are essential parts of critical thinking.

RP-2 Scientific psychology began in Germany in 1879, when Wilhelm Wundt opened the first psychology laboratory.

RP-3 People's self-reports varied, depending on the experience and the person's intelligence and verbal ability.

RP-4 structuralism; functionalism.

RP-5 behaviorism; Freudian.

RP-6 It recaptured the field's early interest in mental processes and made them legitimate topics for scientific study.

RP-7 Natural selection is the process by which nature selects from chance variations the traits that best enable an organism to survive and reproduce in a particular environment.

RP-8 Psychological events often stem from the interaction of nature and nurture, rather than from either of them acting alone.

RP-9 By incorporating three different levels of analysis, the biopsychosocial approach can provide a more complete view than any one perspective could offer.

RP-10 social-cultural; behavioral.

RP-11 i. b, ii. c, iii. a.

RP-12 testing effect.

RP-13 Survey, Question, Read, Retrieve, Review.

Module Test Answers

1. Critical thinking is smart thinking. When evaluating media claims (even about topics you might not know much about), look for empirical evidence. Ask the following questions in your analysis: Are the claims based on scientific findings? Have several studies replicated the findings and confirmed them? Are any experts cited? If so, are they affiliated with a credible institution? Have they conducted or written about scientific

research? What agenda might they have? What alternative explanations are possible?

2. Wilhelm Wundt.
3. a.
4. a.
5. b.
6. The environment (nurture) has an influence on us, but that influence is constrained by our biology (nature). Nature and nurture interact. People predisposed to be very tall (nature), for example, are unlikely to become Olympic gymnasts, no matter how hard they work (nurture).
7. b.
8. positive psychology.
9. d.
10. psychiatrist.
11. c.

MODULE 2: Research Strategies: How

Psychologists Ask and Answer Questions

Retrieval Practice Answers

RP-1 We often suffer from hindsight bias— after we've learned a situation's outcome, that outcome seems familiar and therefore obvious.

RP-2 A good theory *organizes* observed facts and implies hypotheses that offer testable *predictions* and, sometimes, practical applications. It also often stimulates further research.

RP-3 When other investigators are able to replicate an experiment with the same (or stronger) results, scientists can confirm the result and become more confident of its reliability.

RP-4 Case studies involve only one individual or group, so we can't know for sure whether the principles observed would apply to a larger population.

RP-5 Naturalistic observation does not explain behavior, and it does not control for all the factors that may influence behavior. Nevertheless, the descriptions it provides can be revealing, expanding our understanding and paving the way for future studies.

RP-6 An unrepresentative sample is a group that does not represent the population being studied. *Random sampling* helps researchers

form a representative sample, because each member of the population has an equal chance of being included.

RP-7 1. Negative correlation, 2. Positive correlation, 3. Positive correlation, 4. Negative correlation.

RP-8 The team's poor performance was not their typical behavior. The return to their more typical play— their winning streak—may just have been a case of regression toward the mean.

RP-9 In this case, as in many others, a third factor can explain the correlation: Golden anniversaries and baldness both accompany aging.

RP-10 Research designed to prevent the placebo effect randomly assigns participants to an *experimental group* (which receives the real treatment) or to a *control group* (which receives a placebo). A double-blind procedure prevents people's beliefs and hopes from affecting the results, because neither the participants nor those collecting the data know who receives the placebo. A comparison of the results will demonstrate whether the real treatment produces better results than *belief* in that treatment.

RP-11 confounding variables.

RP-12 i. c, ii. a, iii. b.

RP-13 We learn more about the drug's effectiveness when we can compare the results of those who took the drug (the experimental

group) with the results of those who did not (the control group). If we gave the drug to all 1000 participants, we would have no way of knowing whether the drug is serving as a placebo or is actually medically effective.

RP-14 Animal protection legislation, laboratory regulation and inspection, and local and university ethics committees (which screen research proposals) attempt to safeguard animal welfare. International psychological organizations urge researchers involving human participants to obtain *informed consent*, protect them from greater-than-usual harm and discomfort, treat their personal information confidentially, and *debrief* them fully at the end of the experiment. Institutional Review Boards serve to enforce these standards.

Module Test Answers

1. Hindsight bias.

2. d.

3. hypothesis.

4. c.

5. random.

6. negative.

7. scatterplot.

8. a.

9. positive

10. Regression toward the mean is a statistical phenomenon describing the tendency of extreme scores or outcomes to return to average after an unusual event. Without knowing this, we may inaccurately decide the return to average was a result of our own behavior.

11. a.

12. (a) *Alcohol use is associated with violence. (One interpretation: Drinking triggers or unleashes aggressive behavior.)* Perhaps anger triggers drinking, or perhaps the same genes or child-raising practices are predisposing both drinking and aggression. (Here researchers have learned that drinking does indeed trigger aggressive behavior.) (b) *Educated people live longer, on average, than less-educated people. (One interpretation: Education lengthens life and enhances health.)* Perhaps richer people can afford more education and better health care. (Research supports this conclusion.) (c) *Teens engaged in team sports are less likely to use drugs, smoke, have sex, carry weapons, and eat junk food than are teens who do not engage in team sports. (One interpretation: Team sports encourage healthy living.)* Perhaps some third factor explains this correlation—teens who use drugs, smoke, have

sex, carry weapons, and eat junk food may be "loners" who do not enjoy playing on any team. (d) *Adolescents who frequently see smoking in movies are more likely to smoke. (One interpretation: Movie stars' behavior influences impressionable teens.)* Perhaps adolescents who smoke and attend movies frequently have less parental supervision and more access to spending money than other adolescents.

13. experiments.

14. placebo.

15. c.

16. independent variable.

17. b.

18. d.

MODULE 3: Statistical Reasoning in Everyday Life

Retrieval Practice Answers

RP-1 Note how the y-axis of each graph is labeled. The range for the y-axis label in graph (a) is only from 95 to 100. The range for graph (b) is from 0 to 100. All the trucks rank as 95 percent and up, so

almost all are still functioning after 10 years, which graph (b) makes clear.

RP-2 mean; mode; median.

RP-3 range; standard deviation.

RP-4 Averages based on fewer courses are more variable, which guarantees a greater number of extremely low and high marks at the end of the first term.

RP-5 Descriptive; inferential.

Module Test Answers

1. b.

2. d.

3. normal curve.

4. a.

Chapter 2 The Biology of Mind (Modules 4–7)

MODULE 4: Neural and Hormonal Systems

Retrieval Practice Answers

RP-1 They share a focus on the links between the brain and behavior. Phrenology faded because it had no scientific basis—skull bumps don't reveal mental traits and abilities.

RP-2 Thanks to its *neuroplasticity*, our brain changes in response to the experiences we have. Learning and practicing a new skill, like playing an instrument, can promote the development of new neural pathways and cause lasting changes in brain organization.

RP-3 dendrites, cell body, axon.

RP-4 Stronger stimuli (the slap) cause more neurons to fire and to fire more frequently than happens with weaker stimuli (the tap).

RP-5 Neurons send neurotransmitters (chemical messengers) across this tiny space between one neuron's terminal branch and the next neuron's dendrite or cell body.

RP-6 Reuptake occurs when excess neurotransmitters are reabsorbed by the sending neuron. Neurotransmitters can also drift

away or be broken down by enzymes.

RP-7 neurotransmitters.

RP-8 Morphine is an agonist; curare is an antagonist.

RP-9 i. c, ii. a, iii. b.

RP-10 The sympathetic division of the autonomic nervous system would have directed arousal (accelerated heartbeat, inhibited digestion, and so forth), and the parasympathetic division would have directed calming.

RP-11 Responding to signals from the hypothalamus, the pituitary releases hormones that trigger other endocrine glands to secrete hormones, which in turn influence brain and behavior.

RP-12 Both of these communication systems produce chemical molecules that act on the body's receptors to influence our behavior and emotions. The endocrine system, which secretes hormones into the bloodstream, delivers its messages much more slowly than the speedy nervous system, and the effects of the endocrine system's messages tend to linger much longer than those of the nervous system.

Module Test Answers

1. The human brain is uniquely designed to be flexible; it can reorganize after damage and build new pathways based on

experience. This neuroplasticity enables us to adapt to our changing world.

2. axon.
3. c.
4. a.
5. neurotransmitters.
6. b.
7. c.
8. autonomic.
9. central.
10. a.
11. adrenal glands.

MODULE 5: Tools of Discovery: Having Our Head Examined

Retrieval Practice Answers

RP-1 i. b, ii. a, iii. c.

Module Test Answers

1. lesioning.

2. a.

3. a.

4. c.

MODULE 6: Brain Regions and Structures

Retrieval Practice Answers

RP-1 brainstem.

RP-2 (a) cerebellum, (b) thalamus, (c) reticular formation, (d) medulla.

RP-3 The sympathetic nervous system.

RP-4 (a) The *amygdala* is involved in aggression and fear responses. (b) The *hypothalamus* is involved in bodily maintenance, pleasurable rewards, and control of the hormonal systems. (c) The *hippocampus* processes memories of facts and events.

RP-5 The cerebral cortex.

RP-6 (a) The right limbs' opposed activities interfere with each other because both are controlled by the same (left) side of your brain. (b)

Opposite sides of your brain control your left and right limbs, so the reversed motion causes less interference.

RP-7 somatosensory; motor.

RP-8 Association areas are involved in higher mental functions—interpreting, integrating, and acting on information processed in other areas.

Module Test Answers

1. b.
2. d.
3. c.
4. cerebellum.
5. b.
6. amygdala.
7. b.
8. hypothalamus.
9. d.
10. The visual cortex is a neural network of sensory neurons connected via interneurons to other neural networks, including

auditory networks. If you can see and hear, this allows you to integrate visual and auditory information to respond when a friend you recognize greets you at a party.

11. c.

12. frontal.

13. association areas.

MODULE 7: Damage Responses and Brain Hemispheres

Retrieval Practice Answers

RP-1 a) yes, (b) no, (c) green.

Module Test Answers

1. c.

2. ON; HER.

3. a.

4. b.

Chapter 3 Consciousness and the Two-Track Mind (Modules 8–10)

MODULE 8: Basic Consciousness Concepts

Retrieval Practice Answers

RP-1 cognitive neuroscience.

RP-2 Our *selective attention* allows us to focus on only a limited portion of our surroundings. *Inattentional blindness* explains why we don't perceive some things when we are distracted. *Change blindness*, for example, happens when we fail to notice a relatively unimportant change in our environment. These principles help magicians fool us, as they direct our attention elsewhere to perform their tricks.

RP-3 Our mind simultaneously processes information on a conscious track and an unconscious track (dual processing) as we organize and interpret information.

Module Test Answers

1. inattentional blindness.

2. unconscious; conscious.

3. selective.

MODULE 9: Sleep and Dreams

Retrieval Practice Answers

RP-1 With each refugee cycling through the sleep stages independently, at any given time at least one of them will likely be in an easily awakened stage.

RP-2 REM, N1, N2, N3; we typically move through N1, then N2, then N3, then back up through N2 before we experience REM sleep.

RP-3 i. b, ii. c, iii. a.

RP-4 suprachiasmatic; circadian.

RP-5 (1) Sleep has survival value. (2) Sleep helps us restore the immune system, heal from infection, and repair brain tissue. (3) During sleep we consolidate memories. (4) Sleep fuels creativity. (5) Sleep plays a role in the growth process.

RP-6 quick reaction times; gain weight.

RP-7 (1) Freud's wish fulfillment (dreams are a psychic safety valve), (2) information processing (dreams sort the day's events and consolidate memories), (3) neurocognitive function (REM sleep expands neural pathways, preserving memory and processing emotional information), (4) activation synthesis (REM sleep triggers

random neural activity that the mind weaves into stories), and (5) cognitive development (dreams reflect the dreamer's developmental stage).

Module Test Answers

1. circadian rhythm.
2. b.
3. N3.
4. It increases in duration.
5. c.
6. With narcolepsy, the person periodically falls directly into REM sleep, with no warning; with sleep apnea, the person repeatedly awakens during the night.
7. d.
8. The activation-synthesis theory suggests that dreams are the brain's attempt to synthesize random neural activity.
9. The information-processing explanation of dreaming proposes that brain activity during REM sleep enables us to sift through the daily events and activities we have been thinking about *(what one has dwelt on by day).*

10. REM rebound.

MODULE 10: Drugs and Consciousness

Retrieval Practice Answers

RP-1 With repeated exposure to a psychoactive drug, the user's brain chemistry adapts and the drug's effect lessens. Thus, it takes bigger doses to get the desired effect.

RP-2 Unless it becomes compulsive or dysfunctional, simply having a strong interest in shopping is not the same as having a physical addiction to a drug. It typically does not involve obsessive craving in spite of known negative consequences.

RP-3 depressants.

RP-4 Nicotine-withdrawal symptoms include strong cravings, insomnia, anxiety, irritability, and distractibility. However, if your friend sticks with it, the craving and withdrawal symptoms will gradually dissipate over about 6 months.

RP-5 Psychoactive drugs create pleasure by altering brain chemistry. With repeated use of the drug, the user develops tolerance and needs more of the drug to achieve the desired effect. Discontinuing use of the substance then produces painful or psychologically unpleasant withdrawal symptoms.

RP-6 Nicotine is powerfully addictive, and those who start paving the neural pathways when young may find it very hard to stop using it. As a result, tobacco product companies may have lifelong customers. Moreover, evidence suggests that if these companies haven't hooked customers by early adulthood, they most likely won't.

RP-7 Possible explanations include (a) biological factors (a person could have a biological predisposition to both early use and later abuse, or alcohol use could modify a person's neural pathways); (b) psychological factors (early use could establish taste preferences for alcohol); and (c) social-cultural factors (early use could influence enduring habits, attitudes, activities, or peer relationships that could foster alcohol use disorder).

Module Test Answers

1. tolerance.

2. a.

3. Alcohol is a disinhibitor—it makes us more likely to do what we would have done when sober, whether that is being helpful or being aggressive.

4. d.

5. hallucinogenic.

6. a.

7. b.

Chapter 4 Nature, Nurture, and Human Diversity (Modules 11–13)

MODULE 11: Behavior Genetics: Predicting Individual Differences

Retrieval Practice Answers

RP-1 gene, chromosome, nucleus.

RP-2 Researchers use twin and adoption studies to understand how much variation among individuals is due to genetic makeup and how much is due to environmental factors. Some studies compare the traits and behaviors of identical twins (same genes) and fraternal twins (different genes, as in any two siblings). They also compare adopted children with their adoptive and biological parents. Some studies compare the traits and behaviors of twins raised together or separately.

RP-3 genes.

RP-4 i. c, ii. b, iii. a.

Module Test Answers

1. chromosomes.

2. gene.

3. b.

4. c.

5. Identical.

6. b.

7. temperament.

8. Heritability.

9. environments.

MODULE 12: Evolutionary Psychology: Explaining Human Nature and Nurture

Retrieval Practice Answers

RP-1 Over many generations, Belyaev and Trut selected and bred foxes that exhibited a trait they desired: tameness. This process is similar to naturally occurring selection, but it differs in that natural selection is much slower, and normally favors traits (including those arising from mutations) that contribute to reproduction and survival.

RP-2 Evolutionary psychologists theorize that females have inherited their ancestors' tendencies to be more cautious sexually because of the challenges associated with incubating and nurturing offspring. Males have inherited a tendency to be more casual about sex, because their act of fathering requires a smaller investment.

RP-3 (1) It starts with an effect and works backward to propose an explanation. (2) This explanation may overlook the effects of cultural expectations and socialization. (3) Men could use such explanations to rationalize irresponsible behavior toward women.

Module Test Answers

1. differences; commonalities.

2. c.

3. *Natural selection* favors traits and behaviors that enable survival and reproduction. Evolutionary psychologists argue that women are choosier about their mates because of the investment required to conceive, birth, nurse, and protect children. Straight women tend to prefer men who seem capable of supporting and protecting their joint offspring. Men, who have less at stake, tend to be more casual about sex, and straight men tend to prefer women whose traits convey health and fertility.

MODULE 13: Cultural and Gender Diversity: Understanding Nature and

Nurture

Retrieval Practice Answers

RP-1 Adolescents tend to *select* similar others and to sort themselves into like-minded groups. For an athletic teen, this could lead to finding other athletic teens and joining school teams together.

RP-2 Individualists give priority to personal goals over group goals and tend to define their identity in terms of their own personal attributes. Collectivists give priority to group goals over individual goals and tend to define their identity in terms of group identifications.

RP-3 Women; men.

RP-4 seven; puberty.

RP-5 *Gender roles* are social rules or norms for expected behavior for women and men. The norms associated with various roles, including gender roles, vary widely in different cultural contexts, which is proof that we are able to learn and adapt to the social demands of different environments.

RP-6 The biopsychosocial approach considers all the factors that influence our individual development: biological factors (including evolution and our genes, hormones, and brain), psychological factors (including our experiences, beliefs, feelings, and

expectations), and social-cultural factors (including parental and peer influences, cultural individualism or collectivism, and gender norms).

Module Test Answers

1. b.

2. sex; gender.

3. c.

4. Y.

5. d.

6. 10; 12.

7. intersex.

8. b.

9. gender identity.

Chapter 5 Developing Through the Life Span (Modules 14–17)

MODULE 14: Developmental Issues, Prenatal Development, and the Newborn

Retrieval Practice Answers

RP-1 continuity; stages.

RP-2 (1) Stage theory is supported by the work of Piaget (cognitive development), Kohlberg (moral development), and Erikson (psychosocial development). (2) Some traits, such as temperament, exhibit remarkable stability across many years.

RP-3 zygote; fetus; embryo.

RP-4 habituation.

Module Test Answers

1. Cross-sectional studies compare people of different ages at one point in time. Longitudinal studies restudy and retest the same people over a long period of time.

2. continuity/stages.

3. b.

4. c.

5. teratogens.

6. a.

MODULE 15: Infancy and Childhood

Retrieval Practice Answers

RP-1 maturation.

RP-2 Object permanence for the sensorimotor stage, pretend play for the preoperational stage, conservation for the concrete operational stage, and abstract logic for the formal operational stage.

RP-3 i. d, ii. b, iii. c, iv. c, v. a, vi. b.

RP-4 Theory of mind focuses on our ability to understand our own and others' mental state. It enables us to infer other people's feelings, perceptions, and thoughts, and the behaviors these might predict. Those with autism spectrum disorder struggle with this ability.

RP-5 Attachment is the normal process by which we form emotional ties with important others. Imprinting occurs only in certain

animals that have a critical period very early in their development during which they must form their attachments, and they do so in an inflexible manner.

RP-6 The authoritarian style would be described as too hard, the permissive style too soft, the neglectful style too uncaring, and the authoritative style just right. Parents using the authoritative style tend to have children with high self-esteem, self-reliance, self-regulation, and social competence.

Module Test Answers

1. frontal.

2. b.

3. We consciously recall little from before age 4, in part because major brain areas have not yet matured.

4. Infants in Piaget's *sensorimotor stag*e tend to be focused only on their own perceptions of the world and may, for example, be unaware that objects continue to exist when unseen. A child in the *preoperational stage* is still egocentric and incapable of appreciating simple logic, such as the reversibility of operations. A preteen in the *concrete operational stage* is beginning to think logically about concrete events but not about abstract concepts.

5. a.

6. stranger anxiety.

7. Before these studies, many psychologists believed that infants simply became attached to those who nourished them.

MODULE 16: Adolescence and Emerging Adulthood

Retrieval Practice Answers

RP-1 preconventional; postconventional; conventional.

RP-2 Kohlberg's work reflected an individualist worldview, so his theory is less culturally universal than he supposed.

RP-3 i. g, ii. h, iii. c, iv. f, v. e, vi. d, vii. a, viii. b.

Module Test Answers

1. b.

2. formal operational.

3. b.

4. emerging adulthood.

MODULE 17: Adulthood

Retrieval Practice Answers

RP-1 love; work.

RP-2 Challenges: decline of muscular strength, reaction times, stamina, sensory keenness, cardiac output, and immune system functioning. Risk of cognitive decline increases. Rewards: positive feelings tend to grow; negative emotions subside; and anger, stress, worry, and social-relationship problems decrease.

Module Test Answers

1. a.

2. generativity.

3. c.

Chapter 6 Sensation and Perception (Modules 18–20)

MODULE 18: Basic Concepts of Sensation and Perception

Retrieval Practice Answers

RP-1 *Sensation* is the bottom-up process by which your sensory receptors and your nervous system receive and represent stimuli. *Perception* is the top-down process by which your brain creates meaning by organizing and interpreting what your senses detect.

RP-2 *Absolute threshold* is the minimum stimulation needed to detect a particular sound (such as an approaching bike on the sidewalk behind you) 50 percent of the time. *Subliminal stimulation* happens when, without your awareness, your sensory system processes a sound that is below your absolute threshold. A *difference threshold* is the minimum difference needed to distinguish between two stimuli (such as between the sound of a bike and the sound of a runner coming up behind you) 50 percent of the time.

RP-3 The shoes provide constant stimulation. Thanks to *sensory adaptation*, we tend to focus primarily on changing stimuli.

RP-4 *Perceptual set* involves top-down processing, because it draws on your experiences, assumptions, and expectations when interpreting stimuli.

Module Test Answers

1. b.
2. perception.
3. d.
4. just noticeable difference.
5. b.
6. d.
7. a.

MODULE 19: Vision: Sensory and Perceptual Processing

Retrieval Practice Answers

RP-1 For those with vision, the blind spot is on the nose side of each retina, which means that objects to the right may fall onto the right eye's blind spot. Objects to the left may fall on the left eye's blind spot. The blind spot does not normally impair vision, because the

eyes are moving and because one eye catches what the other misses. Moreover, even with only one eye open, the brain provides a perception without a hole in it.

RP-2 rods; cones; color.

RP-3 pupils.

RP-4 The *Young-Helmholtz trichromatic theory* shows that the retina contains color receptors for red, green, and blue. The *opponent-process theory* shows that we have opponent-process cells in the retina and thalamus for red-green, blue-yellow, and white-black. These theories are complementary and outline the two stages of color vision. First, the retina's receptors for red, green, and blue respond to different color stimuli. Second, the receptors' signals are then processed by the opponent-process cells on their way to the visual cortex in the brain.

RP-5 Light waves reflect off the person and travel into the eyes. Receptor cells in the retina convert the light waves' energy into neural impulses sent to the brain. The brain's detector cells and work teams process the subdimensions of this visual input—including color, movement, form, and depth—separately but simultaneously. The brain interprets this information, based on previously stored information and our expectations, and forms a conscious perception of that friend.

RP-6 figure; ground.

RP-7 Gestalt psychologists used this saying to describe our perceptual tendency to organize clusters of sensations into meaningful forms or coherent groups.

RP-8 People typically are able to perceive depth thanks to both binocular cues (such as retinal disparity) and monocular cues (which include relative height, relative size, relative motion, linear perspective, and interposition).

Module Test Answers

1. wavelength.

2. a.

3. c.

4. c.

5. d.

6. The brain constructs this perception of color in two stages. In the first stage, the lemon reflects light energy into the eyes, where it is transformed into neural messages. Three sets of cones, each sensitive to a different light frequency (red, blue, and green) process color. In this case, the light energy stimulates both red-sensitive and green-sensitive cones. In the second stage, opponent-process cells sensitive to paired opposites of color (red/green, blue/yellow, and black/white)

evaluate the incoming neural messages as they pass through the optic nerve to the thalamus and visual cortex. When the yellow-sensitive opponent-process cells are stimulated, the viewer identifies the lemon as yellow.

7. feature detectors.

8. parallel processing.

9. a.

10. d.

11. b.

12. c.

13. monocular.

14. b.

15. b.

16. perceptual adaptation.

MODULE 20: Hearing, Skin, Chemical, and

Body Senses

Retrieval Practice Answers

RP-1 loudness.

RP-2 lower; lower.

RP-3 place theory; frequency theory.

RP-4 c.

RP-5 We have four basic touch senses and five basic taste sensations. But we have no specific smell receptors. Instead, different combinations of odor receptors send messages to the brain, enabling us to recognize some 1 trillion different smells.

RP-6 Kinesthetic receptors, called proprioceptors, are located in our joints, tendons, and muscles. Vestibular sense receptors are located in our inner ear.

RP-7 The ESP event would need to be replicated in other scientific studies.

Module Test Answers

1. cochlea.

2. The outer ear collects sound waves, which are translated into mechanical waves by the *middle ear* and turned into fluid waves

in the *inner ear.* The *auditory nerve* then translates the energy into electrical waves and sends them to the brain, which perceives and interprets the sound.

3. Place; frequency; volley.

4. nociceptors.

5. c.

6. Our experience of pain is influenced by biological factors (such as genetic differences in endorphin production), psychological factors (such as our attention), and social-cultural factors (such as the presence of others).

7. We have specialized receptors for detecting sweet, salty, sour, bitter, and umami tastes. Being able to detect pleasurable tastes enabled our ancestors to seek out energy- or protein-rich foods. Detecting aversive tastes deterred them from eating toxic substances, increasing their chances of survival.

8. Kinesthesia; vestibular sense.

9. Your vestibular sense regulates balance and body positioning through kinesthetic receptors triggered by fluid in your inner ear. Wobbly legs and a spinning world are signs that these receptors are still responding to the ride's turbulence. As your vestibular sense adjusts to solid ground, your balance will be restored.

10. d.

11. d.

Chapter 7 Learning (Modules 21–23)

MODULE 21: Basic Learning Concepts and Classical Conditioning

Retrieval Practice Answers

RP-1 Habits form when we repeat behaviors in a given context and, as a result, learn associations—often without our awareness. For example, we may have eaten a sweet pastry with a cup of coffee often enough to associate the flavor of the coffee with the treat, so that the cup of coffee alone just doesn't seem right anymore!

RP-2 NS = tone before conditioning; US = air puff; UR = blink to air puff; CS = tone after conditioning; CR = blink to tone.

RP-3 The pie (including its taste and aroma) is the US. The photo of the apple pie is the CS. Salivation to the photo is the CR.

RP-4 acquisition; extinction.

RP-5 generalization.

RP-6 If viewing a favorite fictional character (a US) elicits a positive response (a UR), then pairing the US with a new NS (a particular brand of car) could turn that brand of car into a conditioned

stimulus (CS) that also prompts a positive, conditioned response (CR).

RP-7 The US was the loud noise; the UR was the fear response to the noise; the NS was the rat before it was paired with the noise; the CS was the rat after pairing; the CR was fear of the rat.

Module Test Answers

1. information; behaviors.
2. c.
3. conditioned.
4. discrimination.
5. b.
6. A sexual image is a US that triggers a UR of interest or arousal. Before the ad pairs a product with a sexual image, the product is an NS. Over time the product can become a CS that triggers the CR of interest or arousal.

MODULE 22: Operant Conditioning

Retrieval Practice Answers

RP-1 do not; resulting.

RP-2 The baby negatively reinforces her parents' behavior when she stops crying once they grant her wish. Her parents positively reinforce her cries by letting her sleep with them.

RP-3 Spammers are reinforced on a variable-ratio schedule (receiving a response after sending a varying number of emails). Cookie checkers are reinforced on a fixed-interval schedule. Sandwich shop rewards programs use a fixed-ratio schedule.

RP-4 1. PR (positive reinforcement); 2. NP (negative punishment); 3. PP (positive punishment); 4. NR (negative reinforcement).

RP-5 If Joslyn is seeking attention, the teacher's scolding may be reinforcing rather than punishing. To change Joslyn's behavior, her teacher could offer reinforcement (such as praise) each time she behaves well. The teacher might encourage Joslyn toward increasingly appropriate behavior through shaping, or by rephrasing rules as rewards instead of punishments. ("You can use the blocks if you play nicely with the other children" [reward] rather than "You may not use the blocks if you misbehave!" [punishment].)

RP-6 respondent; operant.

Module Test Answers

1. Skinner.

2. shaping.

3. c.

4. They fuss or cry until they are fed. When providing food removes something aversive (baby's cry), the baby negatively reinforces the caregiver's desired behavior (feeding).

5. partial (intermittent).

6. a.

7. variable-interval.

8. c.

MODULE 23: Biology, Cognition, and Learning

Retrieval Practice Answers

RP-1 Garcia and Koelling demonstrated that rats may learn an aversion to tastes, on which their survival depends, but not to sights or sounds.

RP-2 The success of operant conditioning is affected not just by environmental cues, but also by biological and cognitive factors.

RP-3 Hannah may be more likely to speed. Observational learning studies suggest that children tend to do as others do and say what they say.

RP-4 i. c (You've probably learned your way by latent learning), ii. d (Observational learning may have contributed to your brother's imitating the actions seen in the movie), iii. a (Through classical conditioning you have associated the smell with the anticipated tasty result), iv. e (You are biologically predisposed to develop a conditioned taste aversion to foods associated with illness), v. b (Through operant conditioning your dog may have come to associate approaching excitedly with attention, petting, and a treat).

Module Test Answers

1. taste-aversion.
2. This finding supports Darwin's principle that natural selection favors traits that aid survival.
3. cognitive map.
4. latent learning.
5. observational learning.
6. vicarious; vicarious.
7. a.
8. mirror.
9. c.

Chapter 8 Memory (Modules 24–26)

MODULE 24: Studying and Encoding Memories

Retrieval Practice Answers

RP-1 recognition; recall.

RP-2 It would be better to test your memory with *recall* (such as with short-answer or fill-in-the-blank self-test questions) rather than *recognition* (such as with multiple-choice questions). Recalling information is harder than recognizing it. So if you can recall it, that means your retention of the material is better than if you could only recognize it. Your chances of test success are, therefore, greater.

RP-3 The Atkinson-Shiffrin model viewed short-term memory as a temporary holding space for briefly storing recent thoughts and experiences. The newer idea of *working memory* expands our understanding of Atkinson-Shiffrin's short-term memory stage, emphasizing the conscious, active processing that takes place as the brain makes sense of new experiences and links them with our long-term memories.

RP-4 Working memory's two basic functions are active integration of new information with existing long-term memories and focusing of

our spotlight of attention.

RP-5 *Automatic* processing occurs unconsciously (automatically) for such things as the sequence and frequency of a day's events, and reading and comprehending words in our own language(s). *Effortful* processing requires attentive awareness and happens, for example, when we work hard to learn new material in class, or new lines for a play.

RP-6 sensory memory.

RP-7 Although cramming and rereading may lead to short-term gains in knowledge, distributed practice, and repeated self-testing will result in the greatest long-term retention.

RP-8 Making material personally meaningful involves processing at a deep level, because you are processing *semantically*—based on the meaning of the words. Deep processing leads to greater retention.

Module Test Answers

1. recall.

2. encoding; storage; retrieval.

3. a.

4. iconic; echoic.

5. seven.

6. mnemonics.

MODULE 25: Storing and Retrieving Memories

Retrieval Practice Answers

RP-1 The cerebellum and basal ganglia are important for *implicit* memory processing, and the frontal lobes and hippocampus are key to *explicit* memory formation.

RP-2 Our *explicit* conscious memories of facts and episodes differ from our *implicit* memories of skills (such as tying shoelaces) and classically conditioned responses. The parts of the brain involved in explicit memory processing (the frontal lobes and hippocampus) may have sustained damage in the accident, while the parts involved in implicit memory processing (the cerebellum and basal ganglia) appear to have escaped harm.

RP-3 the amygdala.

RP-4 long-term potentiation.

RP-5 *Priming* is the activation (often without our awareness) of associations. Seeing a gun, for example, might temporarily predispose someone to interpret an ambiguous face as threatening or to recall a boss as nasty.

RP-6 serial position.

Module Test Answers

1. a.
2. implicit.
3. c.
4. retrieval cues.
5. Memories are stored within a web of many associations, one of which is mood. When you recall happy moments from your past, you activate these positive links. You may then experience mood-congruent memory and recall other happy moments, which could improve your mood and brighten your interpretation of current events.
6. a.

MODULE 26: Forgetting, Memory Construction, and Improving Memory

Retrieval Practice Answers

RP-1 First, through *encoding failure:* Unattended information never entered our memory system. Second, through *storage decay:* Information fades from our memory. Third, through *retrieval failure:*

We cannot access stored information accurately, sometimes due to interference or motivated forgetting.

RP-2 repress.

RP-3 Real experiences would be confused with those we dreamed. When seeing people we know, we might, therefore, be unsure whether we were reacting to something they previously did or to something we dreamed they did.

RP-4 It will be important to remember the key points agreed upon by most researchers and professional associations: Sexual abuse, injustice, forgetting, and memory construction all happen; recovered memories are common; memories from before age 4 are unreliable; memories claimed to be recovered through hypnosis are especially unreliable; and memories, whether real or false, can be emotionally upsetting.

RP-5 Spend more time rehearsing or actively thinking about the material to boost long-term recall. Consider a study group so you can verbalize your learning. Schedule spaced (not crammed) study times. Make the material personally meaningful, with well-organized and vivid associations. Refresh your memory by returning to contexts and moods to activate retrieval cues. Use mnemonic devices. Minimize proactive and retroactive interference. Plan ahead to ensure a complete night's sleep. Test yourself repeatedly—retrieval practice is a proven retention strategy.

Module Test Answers

1. d.
2. d.
3. retroactive.
4. repression.
5. b.
6. Eliza's immature hippocampus and minimal verbal skills made it impossible for her to encode an explicit memory of the wedding reception at the age of two. It's more likely that Eliza learned information (from hearing the story repeatedly) that she eventually constructed into a memory that feels very real.
7. source amnesia.
8. déjà vu.
9. b.
10. b.

Chapter 9 Thinking and Language (Modules 27–28)

MODULE 27: Thinking

Retrieval Practice Answers

RP-1 If a tragic event, such as a plane crash, makes the news, it is noteworthy and unusual, unlike much more common bad events, such as traffic accidents. Knowing this, we can worry less about unlikely events and think more about improving the safety of our everyday activities. (For example, we can wear a seat belt when in a vehicle and use the crosswalk when walking.)

RP-2 i. b, ii. c, iii. e, iv. d, v. a, vi. f, vii. h, viii. j, ix. i, x. g, xi. k.

Module Test Answers

1. concept.

2. algorithm.

3. Omar will need to guard against *confirmation bias* (searching for support for his own views and ignoring contradictory evidence) as he seeks out opposing viewpoints. Even if Omar encounters new information that disproves his beliefs, *belief perseverance*

may lead him to cling to these views anyway. It will take more compelling evidence to change his political beliefs than it took to create them.

4. c.

5. availability.

6. framing.

7. b.

8. neural networks.

MODULE 28: Language and Thought

Retrieval Practice Answers

RP-1 Two morphemes—*cat* and *s*, and four phonemes—*c, a, t*, and *s*.

RP-2 Chomsky maintained that humans are biologically predisposed to learn the grammar rules of language.

RP-3 Infants typically start developing *receptive language* skills (ability to understand what is said to and about them) around 4 months of age. Then, starting with babbling at 4 months and beyond, infants typically start building *productive language* skills (ability to produce sounds and eventually words).

RP-4 Our brain's *critical period* for language learning is in childhood, when we can absorb language structure almost effortlessly. As we move past that stage in our brain's development, our ability to learn a new language diminishes dramatically.

RP-5 Broca's area; Wernicke's area.

RP-6 linguistic determinism.

RP-7 Mental practice uses visual imagery to mentally rehearse future behaviors, activating some of the same brain areas used during the actual behaviors. Visualizing the details of the process is more effective than visualizing only your end goal.

RP-8 These are definitely communications. But if language consists of words and the grammatical rules we use to combine them to communicate meaning, few scientists would label a dog's barking and yipping as language.

Module Test Answers

1. c.

2. phonemes; morphemes; grammar.

3. telegraphic speech.

4. universal grammar.

5. a.

Chapter 10 Intelligence (Modules 29–31)

MODULE 29: What Is Intelligence?

Retrieval Practice Answers

RP-1 People with savant syndrome have limited mental ability overall but possess one or more exceptional skills. According to Howard Gardner, this suggests that our abilities come in separate packages rather than being fully expressed by one general intelligence that encompasses all of our talents.

RP-2 The CHC theory proposes that there is a general ability based on *two* factors—fluid intelligence and crystallized intelligence—but also that there are more specific abilities, such as reading and writing ability, memory capacity, and processing speed.

Module Test Answers

1. general intelligence.

2. c.

3. analytical; creative; practical.

4. d.

MODULE 30: Intelligence Assessment and Dynamics

Retrieval Practice Answers

RP-1 Binet hoped that determining the child's mental age (the age that typically corresponds to a certain level of performance) would help identify appropriate school placements.

RP-2 $125 (5/4 \times 100 = 125)$

RP-3 aptitude; achievement.

RP-4 A psychological test must be *standardized* (pretested on a representative sample of people), *reliable* (yielding consistent results), and *valid* (measuring and predicting what it is supposed to).

RP-5 disagreement; down; zero; agreement; up.

RP-6 Researcher A should develop a *longitudinal study* to examine how intelligence changes in the same people over the life span. Researcher B should develop a *cross-sectional study* to examine the intelligence of people now at various life stages.

Module Test Answers

1. d. $(9/6 \times 100 = 150)$.

2. c.

3. reliability.

4. c.

5. Writers' work relies more on *Gc* (crystallized intelligence)—accumulated knowledge that increases with age. For top performance, scientists doing research may need more *Gf* (the speedy and abstract reasoning of fluid intelligence), which tends to decrease with age.

MODULE 31: Genetic and Environmental Influences on Intelligence

Retrieval Practice Answers

RP-1 a. (Heritability—variation within a group explained by genetic influences—will increase as environmental variation decreases.)

RP-2 Perfectly equal opportunity would create 100 percent heritability, because genes alone would account for any human differences.

RP-3 A test may be *culturally* biased (unfair) if higher scores are achieved by those with certain cultural experiences. That same test is not scientifically biased as long as it has *predictive validity*—if it predicts what it is supposed to predict. For example, the SAT may favor those with experience in the U.S. school system, but it does still accurately predict U.S. college success.

RP-4 stereotype threat.

Module Test Answers

1. c.

2. a.

3. c.

4. Stereotype threat.

Chapter 11 What Drives Us: Hunger, Sex, Belongingness, and Achievement (Modules 32–35)

MODULE 32: Basic Motivational Concepts

Retrieval Practice Answers

RP-1 (a) Well-practiced runners tend to excel when aroused by competition. (b) High anxiety about a difficult exam may disrupt test-takers' performance.

RP-2 According to Maslow, our drive to meet the physiological needs of hunger and thirst takes priority over our safety needs, prompting us to take risks at times.

Module Test Answers

1. b.

2. a.

3. incentive.

4. Arousal.

5. b.

6. a.

MODULE 33: Hunger

Retrieval Practice Answers

RP-1 low; high.

RP-2 You have learned to respond to the sight and aroma that signal the food about to enter your mouth. Both *physiological* cues (low blood sugar) and *psychological* cues (anticipation of the tasty meal) heighten your experienced hunger.

RP-3 Genetically influenced set/settling points, metabolism, and other factors (such as adequate sleep) influence the way our body burns calories.

Module Test Answers

1. Maslow's hierarchy of needs supports this statement because it addresses the primacy of some motives over others. Once our basic physiological needs are met, safety concerns are addressed next, followed by belongingness and love needs (such as the desire to kiss).

2. set.

3. c.

4. low.

5. basal metabolic.

6. d.

7. Sanjay's plan is problematic. After he gains weight, the extra fat will require less energy to maintain than it did to gain in the first place. Sanjay may have a hard time getting rid of it later, when his metabolism slows down in an effort to retain his body weight.

MODULE 34: Sexual Motivation

Retrieval Practice Answers

RP-1 estrogens; testosterone.

RP-2 sexual dysfunction; paraphilia.

RP-3 Influences include biological factors such as sexual maturity and sex hormones, psychological factors such as environmental stimuli and fantasies, and social-cultural factors such as the values and expectations absorbed from family and the surrounding culture.

RP-4 a, c, d.

RP-5 b, c, e.

Module Test Answers

1. b.

2. b.

3. Sexual dysfunctions are problems that consistently impair arousal or sexual function. Paraphilias are conditions, which may be classified as psychological disorders, in which sexual arousal is associated with nonhuman objects, the suffering of self or others, and/or nonconsenting persons.

4. does; doesn't.

5. c.

6. Researchers have found no evidence that any environmental factor (parental relationships, childhood experiences, peer relationships, or dating experiences) influences the development of our sexual orientation.

MODULE 35: Affiliation and Achievement

Retrieval Practice Answers

RP-1 They engaged in more self-defeating behaviors and displayed more disparaging and aggressive behavior. These students' basic *need to belong* seems to have been disrupted.

RP-2 strengthen; increase.

RP-3 self-discipline *(grit).*

Module Test Answers

1. c.

2. Monitor our time spent online, as well as our feelings about that time. Change our online status to unavailable when we don't want to be contacted. Check our devices less often. Get outside and away from technology regularly.

3. should; should.

Chapter 12 Emotions, Stress, and Health (Modules 36–40)

MODULE 36: Introduction to Emotion

Retrieval Practice Answers

RP-1 simultaneously; sequentially (first the physiological response, and then the experienced emotion).

RP-2 cognitive.

RP-3 Zajonc and LeDoux suggested that we experience some emotions without any conscious, cognitive appraisal. Lazarus, Schachter, and Singer emphasized the importance of appraisal and cognitive labeling in our experience of emotion.

RP-4 The *sympathetic division* of the ANS arouses us for more intense experiences of emotion, pumping out the stress hormones epinephrine and norepinephrine to prepare our body for fight or flight. The *parasympathetic division* of the ANS takes over when a crisis passes, restoring our body to a calm physiological and emotional state.

Module Test Answers

1. James-Lange.

2. b.

3. c.

4. A polygraph measures emotion-linked physiological changes, such as in perspiration, heart rate, and breathing. But the measure cannot distinguish between emotions with similar physiology (such as anxiety and guilt).

MODULE 37: Expressing Emotion

Retrieval Practice Answers

RP-1 Women.

RP-2 Some facial expressions, such as those of happiness and sadness, tend to be universally recognizable and thus likely rooted in biology. Context and culture, however, can influence the way facial expressions are interpreted. Like most psychological events, facial expressions are best understood not only as biological and cognitive phenomena, but also as social-cultural phenomena.

RP-3 (a) Most students report feeling more happy than sad when their cheeks are raised upward. (b) Most students report feeling more sad than happy when their cheeks are pulled downward.

Module Test Answers

1. facial feedback.

2. Aiden's droopy posture could negatively affect his mood thanks to the behavior feedback effect, which tends to make us feel the way we act.

MODULE 38: Experiencing Emotion

Retrieval Practice Answers

RP-1 b.

RP-2 a. Age does NOT effectively predict happiness levels. Better predictors are personality traits, sleep and exercise, and religious faith.

Module Test Answers

1. d.

2. Positive.

3. b.

4. relative deprivation.

MODULE 39: Stress and Illness

Retrieval Practice Answers

RP-1 sympathetic; increase; muscles; fight-or-flight.

RP-2 psychoneuroimmunology.

RP-3 Stress tends to reduce our immune system's ability to function properly, so that higher stress generally leads to greater risk of physical illness.

RP-4 Feeling angry and negative much of the time.

Module Test Answers

1. b.

2. d.

3. resistance; exhaustion.

4. tend; befriend.

5. immune system.

6. Type A people frequently experience negative emotions (anger, impatience), during which the sympathetic nervous system diverts blood away from the liver. This leaves fat and cholesterol circulating in the bloodstream for deposit near the heart and

other organs, increasing the risk of heart disease and other health problems. Thus, Type A people actually harm themselves by directing anger at others.

MODULE 40: Health and Coping

Retrieval Practice Answers

RP-1 problem; emotion.

RP-2 b.

RP-3 Aerobic exercise, relaxation, meditation, and active spiritual engagement.

Module Test Answers

1. emotion.

2. b.

3. internal.

4. By allowing ourselves to feel our natural negative and positive emotions, we are better able to navigate the realities of our lives—including good times and bad times. Suppressing or ignoring our feelings has negative consequences, leaving us less able to manage stress or build authentic relationships.

5. d.

6. aerobic.

7. c.

Chapter 13 Social Psychology (Modules 41–44)

MODULE 41: Social Thinking

Retrieval Practice Answers

RP-1 By attributing the other person's behavior to the person ("What a terrible driver") and his own to the situation ("These roads are awful"), Marco has exhibited the *fundamental attribution error.*

RP-2 Our attitudes often influence our actions as we behave in ways consistent with our beliefs. However, our actions also influence our attitudes; we come to believe in what we have done.

RP-3 cognitive dissonance.

RP-4 Avoid yelling at, humiliating, or boring your audience. It's more effective to identify shared values, appeal to others' admirable motives, make your message vivid and repeat it, and get your audience to actively engage with your message.

Module Test Answers

1. fundamental attribution.

2. foot-in-the-door.

3. *Cognitive dissonance theory* best supports this suggestion. If Jamala acts confident, her behavior will contradict her negative self-thoughts, creating cognitive dissonance. To relieve the tension, Jamala may realign her attitudes with her actions by viewing herself as more outgoing and confident.

4. peripheral.

MODULE 42: Social Influence

Retrieval Practice Answers

RP-1 a.

RP-2 normative social influence.

RP-3 Stanley Milgram.

RP-4 The Milgram studies showed that people were most likely to follow orders when the experimenter was nearby and was perceived to be a legitimate authority figure, the authority figure was supported by a powerful or prestigious institution, the victim was depersonalized or at a distance, and there were no models for defiance.

RP-5 This improved performance in the presence of others is most likely to occur with a well-learned task, because the added arousal caused by an audience tends to strengthen the most likely response.

This also predicts poorer performance on a difficult task in others' presence.

RP-6 social loafing.

RP-7 The anonymity provided by the masks, combined with the arousal of the contentious setting, might create deindividuation (lessened self-awareness and self-restraint).

RP-8 group polarization.

RP-9 groupthink.

Module Test Answers

1. c.

2. a.

3. The presence of a large audience generates arousal and strengthens Dr. Huang's most likely response: enhanced performance on a task he has mastered (teaching music history) and impaired performance on a task he finds difficult (statistics).

4. deindividuation.

5. group polarization.

MODULE 43: Antisocial Relations

Retrieval Practice Answers

RP-1 scapegoat.

RP-2 Our biology (our genes, neural systems, and biochemistry—including testosterone and alcohol levels) influences our aggressive tendencies. Psychological factors (such as frustration, previous rewards for aggressive acts, and observation of others' aggression) can trigger any aggressive tendencies we may have. Social influences, such as exposure to violent media, and cultural influences, such as whether we've grown up in a "culture of honor" or a father-absent home, can also affect our aggressive responses.

Module Test Answers

1. stereotypes.

2. b.

3. more.

4. d.

5. frustration-aggression principle.

6. c.

7. c.

8. c.

MODULE 44: Prosocial Relations

Retrieval Practice Answers

RP-1 mere exposure effect.

RP-2 Being physically attractive tends to elicit positive first impressions. People tend to assume that attractive people are healthier, happier, more sensitive, more successful, and more socially skilled than others are.

RP-3 Emotions consist of (1) physical arousal and (2) our interpretation of that arousal. Researchers have found that any source of arousal may be interpreted as passion in the presence of a desirable person.

RP-4 equity; self-disclosure.

RP-5 In the presence of others, an individual is less likely to notice a situation, correctly interpret it as an emergency, and take responsibility for offering help. The inaction of neighbors who heard Kitty Genovese's cries for help demonstrated this *bystander effect,* as each witness assumed many others were also aware of the event.

RP-6 Sports fans may feel they are a part of an *ingroup* (fans of their preferred team) that sets itself apart from an *outgroup* (fans of the archrival team). Ingroup bias tends to develop, leading to prejudice and the view that the outgroup "deserves" misfortune. So, the archrival team's loss may seem justified. In conflicts, this kind of thinking is problematic, especially when each side in the conflict develops *mirror-image perceptions* of the other (distorted, negative images that are ironically similar).

RP-7 Peacemakers should encourage equal-status contact, cooperation to achieve *superordinate goals* (shared goals that override differences), understanding through communication, and reciprocated conciliatory gestures (each side gives a little).

Module Test Answers

1. mere exposure.
2. companionate; passionate.
3. d.
4. c.
5. mirror-image.
6. superordinate.

Chapter 14 Personality (Modules 45–47)

MODULE 45: Introduction to Personality and Psychodynamic Theories

Retrieval Practice Answers

RP-1 ego; id; superego.

RP-2 fixation.

RP-3 unconsciously; anxiety.

RP-4 Freud is credited with first drawing attention to the importance of childhood experiences, to the existence of the unconscious mind, and to our self-protective defense mechanisms. Freud's theory has been criticized as not scientifically testable and offering after-the-fact explanations, focusing too much on sexual conflicts in childhood, and being based on the idea of repression, which has not been supported by modern research.

RP-5 Today's psychodynamic theorists and therapists still use Freud's interviewing techniques, and they still tend to focus on childhood experiences and attachments, unresolved conflicts, and unconscious influences. However, they are not likely to dwell on

fixation at any psychosexual stage, or the idea that sexual issues are the basis of our personality.

RP-6 Projective.

Module Test Answers

1. c.
2. superego.
3. b.
4. anxiety.
5. repression.
6. d.
7. a.
8. a.

MODULE 46: Humanistic Theories and Trait Theories

Retrieval Practice Answers

RP-1 The humanistic theories sought to turn psychology's attention away from drives and conflicts and toward our growth potential.

This movement's focus on the way people strive for self-determination and self-realization was in contrast to Freudian theory and strict behaviorism.

RP-2 To be *empathic* is to share and mirror another person's feelings. Carl Rogers believed that people nurture growth in others by being empathic. Abraham Maslow proposed that *self-actualization* is the motivation to fulfill one's potential, and one of the ultimate psychological needs (another is self-transcendence).

RP-3 extraversion–introversion and emotional stability–instability.

RP-4 The Big Five personality factors are *o*penness, *c*onscientiousness, *e*xtraversion, *a*greeableness, and *n*euroticism (emotional stability vs. instability): OCEAN. These factors may be objectively measured, they are relatively stable over the life span, and they apply fairly well to all cultures in which they have been studied.

RP-5 Our scores on personality tests predict our *average* behavior across many situations much better than they predict our specific behavior in any given situation.

Module Test Answers

1. d.

2. Rogers might assert that the criminal was raised in an environment lacking acceptance (unconditional positive regard), genuineness, and empathy, which inhibited psychological growth and led to a negative self-concept.

3. unconditional positive regard.

4. Trait.

5. c.

6. b.

7. b.

MODULE 47: Social-Cognitive Theories and the Self

Retrieval Practice Answers

RP-1 social-cognitive; reciprocal determinism.

RP-2 To predict someone's future behavior, examine the person's past behavior patterns in similar situations.

RP-3 People who feel confident in their abilities tend to be outgoing, responsible, and open to new experiences, and are often happier, less anxious, and less lonely. Inflated self-esteem can lead to the

Dunning-Kruger effect, self-serving bias, greater aggression, and narcissism.

RP-4 self-serving bias.

RP-5 Defensive; Secure.

Module Test Answers

1. a.
2. social-cognitive.
3. spotlight effect.
4. b.
5. Yes, if that self-love is of the *secure* type. Secure self-esteem promotes a focus beyond the self and a higher quality of life. Excessive self-love may promote artificially high or defensive self-esteem, which is fragile; perceived threats may be met with anger or aggression.

Chapter 15 Psychological Disorders Modules (48–53)

MODULE 48: Introduction to Psychological Disorders

Retrieval Practice Answers

RP-1 dysfunctional or maladaptive.

RP-2 Some psychological disorders are culture-specific. For example, anorexia nervosa occurs mostly in Western cultures, and *taijin kyofusho* appears largely in Japan. Other disorders, such as major depressive disorder and schizophrenia, are universal—they occur in all cultures.

RP-3 Biological, psychological, and social-cultural influences combine to produce psychological disorders. This approach helps us understand that our well-being is affected by our genes, brain functioning, inner thoughts and feelings, and the influences of our social and cultural environment.

RP-4 Therapists and others apply disorder labels to communicate with one another using a common language, and to share concepts during research. Clients may benefit from knowing that they are not the only ones with these symptoms. The dangers of labeling people

are that (1) overly broad classifications may pathologize typical behavior, and (2) the labels can trigger assumptions that will change people's behavior toward those who are labeled.

RP-5 false.

RP-6 true.

RP-7 Poverty-related stresses can help trigger disorders, but disabling disorders can also contribute to poverty. Thus, poverty and disorder are often a chicken-and-egg situation; it's hard to know which came first.

Module Test Answers

1. major depressive disorder.

2. No. Robert's behavior is unusual, causes distress, and may make him a few minutes late on occasion, but it does not appear to significantly disrupt his ability to function. Like most of us, Robert demonstrates some unusual behaviors. Since they are not disabling or dysfunctional, they do not suggest a psychological disorder.

3. medical.

4. There are various culture-linked disorders, including *susto* (in Latin America), *taijin kyofusho* (in Japan), and eating disorders (in food-abundant Western cultures).

5. c.

6. Critics have expressed concerns about the negative effects of labeling by the DSM and other classification systems. Labels have the potential to be both subjective and stigmatizing. Further, critics suggest that the DSM-5 cast too wide a net on disorders, pathologizing typical behavior.

7. Men; women.

8. d.

MODULE 49: Anxiety Disorders, Obsessive-Compulsive and Related Disorders, Trauma- and Stressor-Related Disorders, and Somatic Symptom and Related Disorders

Retrieval Practice Answers

RP-1 generalized anxiety.

RP-2 panic.

RP-3 specific phobia.

RP-4 obsessive-compulsive.

RP-5 posttraumatic stress.

RP-6 Somatic means "relating to the body"; somatic symptom disorders produce distressing bodily symptoms that have no apparent physical cause.

RP-7 Biological factors include inherited temperament and other gene variations; experience-altered brain pathways; and outdated, inherited responses that had survival value for our distant ancestors.

Module Test Answers

1. c.
2. specific phobia.
3. obsessive-compulsive.
4. b.
5. c.

MODULE 50: Depressive Disorders and Bipolar Disorders

Retrieval Practice Answers

RP-1 Many factors contribute to depression, including the biological influences of genetics and brain function. Social-cognitive factors

also matter, including the interaction of explanatory style, mood, our responses to stressful experiences, changes in our patterns of thinking and behaving, and cultural influences. Depression involves the whole body and may disrupt sleep, energy levels, and concentration.

Module Test Answers

1. women's; men's.

2. a.

3. norepinephrine; serotonin.

4. social-cognitive.

MODULE 51: Schizophrenia

Retrieval Practice Answers

RP-1 negative; positive.

RP-2 Biological factors include abnormalities in brain structure and function and a genetic predisposition to the disorder. Environmental factors such as nutritional deprivation, exposure to virus, and maternal stress contribute to activating the genes that increase risk. Exposure to many environmental triggers can increase the odds of developing schizophrenia.

Module Test Answers

1. Schizophrenia involves the altered perceptions, emotions, and behaviors of a mind split from reality. It does not involve the rapid changes in mood or identity suggested by this comparison.

2. b.

3. hallucination.

4. a.

MODULE 52: Dissociative, Personality, and Eating Disorders

Retrieval Practice Answers

RP-1 The psychodynamic explanation of DID symptoms is that they are defenses against anxiety generated by unacceptable urges. The learning perspective attempts to explain these symptoms as behaviors that have been reinforced by relieving anxiety.

RP-2 Twin and adoption studies show that biological relatives of people with antisocial personality disorder are at increased risk for antisocial behavior. Researchers have also observed differences in the brain activity and structure of antisocial criminals. Negative environmental factors, such as poverty or childhood abuse, may

channel genetic traits such as fearlessness in more dangerous directions—toward aggression and away from social responsibility.

RP-3 anorexia nervosa; bulimia nervosa.

Module Test Answers

1. c.
2. c.
3. b.
4. b.

MODULE 53: Neurodevelopmental Disorders

Retrieval Practice Answers

RP-1 To be diagnosed with an intellectual developmental disorder, a person's intelligence test score must be in the lowest 3 percent of the general population, or about 70 or below. In addition, the person must have difficulty adapting to the normal demands of independent living: conceptual (language, reading, and concepts of money, time, and number); social (interpersonal skills, being socially responsible, following basic rules and laws, not being

victimized); and practical (health and personal care, occupational skill, and travel).

Module Test Answers

1. c.

2. Several studies have revealed "underconnectivity" in the brains of people with ASD, which makes it more difficult for different parts of the brain to work together and integrate information. Those with ASD are also less imitative and show less activity in brain areas involved in mirroring others' actions.

3. The DSM has broadened the diagnostic criteria for ADHD, leading to an increase in diagnoses without concurrent changes in children's attentional behavior. Critics suggest that these criteria are now too broad and may pathologize behaviors, labeling everyday childish rambunctiousness as a disorder.

Chapter 16 Therapy (Modules 54–56)

MODULE 54: Introduction to Therapy and the Psychological Therapies

Retrieval Practice Answers

RP-1 transference; resistance; interpretation.

RP-2 A psychodynamic therapist might be more interested in helping the child develop insight about the underlying problems that have caused the bed-wetting response. A behavior therapist would be more likely to agree with Mowrer that the bed-wetting *is* the problem, and that counterconditioning the unwanted behavior would indeed bring emotional relief.

RP-3 The *insight therapies*—psychodynamic and humanistic therapies—seek to relieve problems by providing an understanding of their origins. *Behavior therapies* assume the problem behavior *is* the problem and treat it directly, paying less attention to its origins.

RP-4 If a behavior can be learned, it can be *un*learned and replaced by other, more adaptive responses.

RP-5 classical; operant.

RP-6 By reflecting people's feelings in a nondirective setting, the *humanistic therapies* attempt to foster personal growth by helping people become more self-aware and self-accepting. By making people aware of self-defeating patterns of thinking, *cognitive therapies* guide them toward more adaptive ways of thinking about themselves and their world.

RP-7 cognitive therapy.

RP-8 *Cognitive-behavioral therapy* helps people change self-defeating thinking and behavior. It has been shown to be effective for those with anxiety disorders, obsessive-compulsive and related disorders, depressive disorders, bipolar disorders, ADHD, eating disorders, and alcohol or other substance use disorders.

Module Test Answers

1. a.
2. Insight.
3. d.
4. active listening.
5. c.
6. counterconditioning.
7. systematic desensitization.

8. Behavior therapies are often the best choice for treating specific phobias. Viewing Rico's fear of the highway as a learned response, a behavior therapist might help Rico learn to replace his anxious response to highway driving with a relaxation response.

9. token economy.

10. d.

11. Cognitive-behavioral.

12. b.

MODULE 55: Evaluating Psychotherapies

Retrieval Practice Answers

RP-1 The *placebo effect* is the healing power of belief in a treatment. Patients and therapists who expect a treatment to be effective may believe it was effective.

RP-2 are.

RP-3 When using an evidence-based approach, therapists make decisions about treatment based on research evidence, clinical expertise, and knowledge of the client.

RP-4 more.

RP-5 ethical.

Module Test Answers

1. c.
2. d.
3. research evidence, clinical expertise, and knowledge of the patient.
4. hope.

MODULE 56: The Biomedical Therapies and Preventing Psychological Disorders

Retrieval Practice Answers

RP-1 Exercise regularly, get enough sleep, get more exposure to light (get outside or use a light box), nurture important relationships, redirect negative thinking, and eat a diet rich in omega-3 fatty acids.

RP-2 Researchers assign people to treatment and no-treatment conditions to see if those who receive the drug therapy improve more than those who don't. Double-blind controlled studies are most effective. If neither the therapist nor the client knows which participants have received the drug treatment, then any difference

between the treated and untreated groups will reflect the drug treatment's actual effect.

RP-3 antidepressants; antipsychotic.

RP-4 electroconvulsive therapy; direct current; magnetic; deep brain.

RP-5 Psychological or biomedical therapies attempt to relieve people's suffering from psychological disorders. Preventive mental health attempts to prevent suffering by identifying and eliminating the conditions that cause disorders, as well as by building resilience.

Module Test Answers

1. c.
2. antianxiety.
3. lithium.
4. b.
5. d.

Appendix C Psychology at Work

Work and Life Satisfaction

Retrieval Practice Answers

RP-1 We become more likely to view our work as socially useful, and we experience higher self-esteem, feelings of competence, and overall well-being.

RP-2 (1) Interviewers may presume people are what they seem to be in interviews. (2) Interviewers' preconceptions and moods color how they perceive interviewees' responses. (3) Interviewers judge people relative to other recent interviewees. (4) Interviewers tend to track the successful careers of those they hire, not the successful careers of those they reject. (5) Interviews tend to disclose prospective workers' good intentions, not their habitual behaviors.

RP-3 *Transformational leaders* are able to inspire others to share a vision and commit themselves to a group's mission. They tend to be naturally extraverted and set high standards.

RP-4 To develop safer machines and work environments, human factors psychologists stay mindful of the curse of knowledge—the tendency for experts to mistakenly assume that others share their knowledge.

Module Test Answers

1. flow.

2. Personnel; human factors.

3. a.

4. d.

5. Focusing on SMART goals—goals that are *s*pecific, *m*easurable, *a*ctionable, *r*ealistic, and *t*ime-bound (such as maintaining a regular study schedule)—will be more helpful than focusing on more distant general goals (such as earning a good grade in this class).

6. transformational.

7. c.

8. d.

Glossary

absolute threshold
the minimum stimulus energy needed to detect a particular stimulus 50 percent of the time.

accommodation
(1) adapting our current schemas (understandings) to incorporate new information. (2) the process by which the eye's lens changes shape to focus near or far objects on the retina.

achievement motivation
the desire for significant accomplishment, for mastery of skills or ideas, for control, and for attaining a high standard.

achievement test
a test designed to assess what a person has learned.

acquisition
in classical conditioning, the initial stage—when one links a neutral stimulus and an unconditioned stimulus so that the neutral stimulus begins triggering the conditioned response. (In operant conditioning, the strengthening of a reinforced response.)

action potential
a neural impulse; a brief electrical charge that travels down an axon.

active listening

empathic listening in which the listener echoes, restates, and seeks clarification. A feature of Rogers' person-centered therapy.

acute schizophrenia
(also called *reactive schizophrenia*) a form of schizophrenia that can begin at any age, frequently occurs in response to a traumatic event, and from which recovery is much more likely.

adaptation-level phenomenon
our tendency to form judgments (of sounds, of lights, of income) relative to a neutral level defined by our prior experience.

addiction
an everyday term for compulsive substance use (and sometimes for dysfunctional behavior patterns, such as out-of-control gambling) that continues despite harmful consequences. (See also *substance use disorder.*)

adolescence
the transition period from childhood to young adulthood, extending from puberty to independence.

adrenal [ah-DREEN-el] glands
a pair of endocrine glands that sits just above the kidneys and secretes hormones (epinephrine and norepinephrine) that help arouse the body in times of stress.

aerobic exercise
sustained exercise that increases heart and lung fitness; also helps alleviate depression and anxiety.

affiliation need
the need to build and maintain relationships and to feel connected to a group.

aggression

any physical or verbal behavior intended to harm someone physically or emotionally.

agonist
a molecule that increases a neurotransmitter's action.

AIDS (acquired immune deficiency syndrome)
a life-threatening condition caused by the *human immunodeficiency virus (HIV)*, a sexually transmitted infection. AIDS depletes the immune system, leaving the person vulnerable to infections.

alcohol use disorder
(commonly known as *alcoholism*) alcohol use marked by a combination of symptoms that may include tolerance, withdrawal, and a drive to continue problematic use.

algorithm
a methodical, logical rule, or procedure that guarantees solving a particular problem. Contrasts with the usually speedier—but also more error-prone—use of *heuristics*.

all-or-none response
a neuron's reaction of either firing (with a full-strength response) or not firing.

alpha waves
the relatively slow brain waves of a relaxed, awake state.

altruism
unselfish regard for the welfare of others.

Alzheimer's disease
a neurocognitive disorder marked by neural plaques, often with onset after age 80, and entailing a progressive decline in memory and other cognitive abilities.

amphetamines
drugs (such as *methamphetamine*) that stimulate neural activity, causing accelerated body functions and associated energy and mood changes.

amygdala [uh-MIG-duh-la]
two almond-shaped neural clusters in the limbic system; linked to emotion.

androgyny
blending traditionally masculine and traditionally feminine psychological characteristics.

anorexia nervosa
an eating disorder in which a person (most often an adolescent female) maintains a starvation diet despite being significantly underweight, and has an inaccurate self-perception; sometimes accompanied by excessive exercise.

antagonist
a molecule that inhibits or blocks a neurotransmitter's action.

anterograde amnesia
an inability to form new memories.

antianxiety drugs
drugs used to control anxiety and agitation.

antidepressant drugs
drugs used to treat depressive disorders, anxiety disorders, obsessive-compulsive and related disorders, and posttraumatic stress disorder. (Several widely used antidepressant drugs are *selective serotonin reuptake inhibitors—SSRIs.*)

antipsychotic drugs
drugs used to treat schizophrenia and other psychotic disorders.

antisocial behavior

negative, destructive, harmful behavior. The opposite of prosocial behavior.

antisocial personality disorder
a personality disorder in which a person (usually a man) exhibits a lack of conscience for wrongdoing, even toward friends and family members; may be aggressive and ruthless or a clever con artist.

anxiety disorders
a group of disorders characterized by excessive fear and anxiety and related maladaptive behaviors.

aphasia
impairment of language, usually caused by left hemisphere damage either to Broca's area (impairing speaking) or to Wernicke's area (impairing understanding).

applied research
a scientific study that aims to solve practical problems.

approach and avoidance motives
the drive to move toward (approach) or away from (avoid) a stimulus.

aptitude test
a test designed to predict a person's future performance; *aptitude* is the capacity to learn.

asexual
having no sexual attraction toward others.

assimilation
interpreting our new experiences in terms of our existing schemas.

association areas

areas of the cerebral cortex that are not involved in primary motor or sensory functions; rather, they are involved in higher mental functions such as learning, remembering, thinking, and speaking.

associative learning
learning that certain events occur together. The events may be two stimuli (as in classical conditioning) or a response and its consequence (as in operant conditioning).

attachment
an emotional tie with others; shown in young children by their seeking closeness to caregivers and showing distress on separation.

attention-deficit/hyperactivity disorder (ADHD)
a psychological disorder marked by extreme inattention and/or hyperactivity and impulsivity.

attitude
feelings, often influenced by our beliefs, that predispose us to respond in a particular way to objects, people, and events.

attribution theory
the theory that we explain someone's behavior by crediting either the situation or the person's disposition.

audition
the sense or act of hearing.

autism spectrum disorder (ASD)
a disorder that appears in childhood and is marked by limitations in communication and social interaction, and by rigidly fixated interests and repetitive behaviors.

automatic processing

unconscious encoding of incidental information, such as space, time, and frequency, and of familiar or well-learned information, such as sounds, smells, and word meanings.

autonomic [aw-tuh-NAHM-ik] nervous system (ANS)
the part of the peripheral nervous system that controls the glands and the muscles of the internal organs (such as the heart). Its *sympathetic* division arouses; its *parasympathetic* division calms.

availability heuristic
judging the likelihood of events based on their availability in memory; if instances come readily to mind (perhaps because of their vividness), we presume such events are common.

aversive conditioning
associates an unpleasant state (such as nausea) with an unwanted behavior (such as drinking alcohol).

axon
the segmented neuron extension that passes messages through its branches to other neurons, muscles, or glands.

babbling stage
the stage in speech development, beginning around 4 months, during which an infant spontaneously utters various sounds that are not all related to the household language.

barbiturates
drugs that depress central nervous system activity, reducing anxiety but impairing memory and judgment.

basal metabolic rate
the body's resting rate of energy output.

basic research
pure science that aims to increase the scientific knowledge base.

basic trust
according to Erik Erikson, a sense that the world is predictable and trustworthy; said to be formed during infancy by appropriate experiences with responsive caregivers.

behavior feedback effect
the tendency of behavior to influence our own and others' thoughts, feelings, and actions.

behavior genetics
the study of the relative power and limits of genetic and environmental influences on behavior.

behavior therapy
therapy that uses learning principles to reduce unwanted behaviors and increase desirable behaviors.

behaviorism
the view that psychology (1) should be an objective science that (2) studies behavior without reference to mental processes. Most research psychologists today agree with (1) but not with (2).

belief perseverance
the persistence of one's initial conceptions after the basis on which they were formed has been discredited.

Big Five factors
researchers identified five factors—*openness, conscientiousness, extraversion, agreeableness,* and *neuroticism*—that describe personality. (Also called the *five-factor model.*)

binge-eating disorder
significant binge-eating episodes, followed by distress, disgust, or guilt, but without the compensatory behavior that marks bulimia nervosa.

binocular cue
a depth cue, such as retinal disparity, that depends on the use of two eyes.

biological psychology
the scientific study of the links between biological (genetic, neural, hormonal) and psychological processes. Some biological psychologists call themselves *neuroscientists, neuropsychologists, behavior geneticists, physiological psychologists,* or *biopsychologists.*

biomedical therapy
prescribed medications or procedures that act directly on the person's physiology.

biopsychosocial approach
an integrated approach that incorporates biological, psychological, and social-cultural levels of analysis.

bipolar disorders
disorders in which a person experiences the overexcited state of mania (or milder hypomania), and usually experiences periods of depression. (Formerly called *manic-depressive disorder.*)

blind spot
the point at which the optic nerve leaves the eye, creating a "blind" spot because no receptor cells are located there.

blindsight
a condition in which a person can respond to a visual stimulus without consciously experiencing it.

bottom-up processing

information processing that begins with the sensory receptors and works up to the brain's integration of sensory information.

brainstem
the central core of the brain, beginning where the spinal cord swells as it enters the skull; the brainstem is responsible for automatic survival functions.

Broca's area
a frontal lobe brain area, usually in the left hemisphere, that helps control language expression by directing the muscle movements involved in speech.

bulimia nervosa
an eating disorder in which a person's binge eating (usually of high-calorie foods) is followed by weight-loss-promoting behavior, such as vomiting, laxative use, fasting, or excessive exercise.

bystander effect
the tendency for any given bystander to be less likely to give aid if other bystanders are present.

Cannon-Bard theory
the theory that an emotion-arousing stimulus simultaneously triggers (1) physiological responses and (2) the subjective experience of emotion.

case study
a descriptive technique in which one individual or group is studied in depth in the hope of revealing universal principles.

Cattell-Horn-Carroll (CHC) theory
the theory that our intelligence is based on general intelligence *(g)* as well as specific abilities, bridged by fluid intelligence *(Gf)* and crystallized intelligence *(Gc)*.

cell body

the part of a neuron that contains the nucleus; the cell's life-support center.

central nervous system (CNS)
the brain and spinal cord.

central route persuasion
occurs when interested people's thinking is influenced by considering evidence and arguments.

cerebellum [sehr-uh-BELL-um]
the hindbrain's "little brain" at the rear of the brainstem; functions include processing sensory input, coordinating movement output and balance, and enabling nonverbal learning and memory.

cerebral [seh-REE-bruhl] cortex
the intricate fabric of interconnected neural cells covering the forebrain's cerebral hemispheres; the body's ultimate control and information-processing center.

change blindness
failing to notice changes in the environment; a form of *inattentional blindness.*

chromosomes
threadlike structures made of DNA molecules that contain the genes.

chronic schizophrenia
(also called *process schizophrenia*) a form of schizophrenia in which symptoms usually appear by late adolescence or early adulthood. As people age, psychotic episodes last longer and recovery periods shorten.

chunking
organizing items into familiar, manageable units; often occurs automatically.

circadian [ser-KAY-dee-an] rhythm

our biological clock; regular bodily rhythms (for example, of temperature and wakefulness) that occur on a 24-hour cycle.

classical conditioning
a type of learning in which we link two or more stimuli; as a result, to illustrate with Pavlov's classic experiment, the first stimulus (a tone) comes to elicit behavior (drooling) in anticipation of the second stimulus (food).

clinical psychology
a branch of psychology that studies, assesses, and treats people with psychological disorders.

cocaine
a powerful and addictive stimulant derived from the coca plant; produces temporarily increased alertness and euphoria.

cochlea [KOHK-lee-uh]
a coiled, bony, fluid-filled tube in the inner ear; sound waves traveling through the cochlear fluid trigger nerve impulses.

cochlear implant
a device for converting sounds into electrical signals and stimulating the auditory nerve through electrodes threaded into the cochlea.

cognition
all the mental activities associated with thinking, knowing, remembering, and communicating.

cognitive dissonance theory
the theory that we act to reduce the discomfort (dissonance) we feel when two of our thoughts (cognitions) are inconsistent. For example, when we become aware that our attitudes and our actions clash, we can reduce the resulting dissonance by changing our attitudes.

cognitive learning
the acquisition of mental information, whether by observing events, by watching others, or through language.

cognitive map
a mental representation of the layout of one's environment. For example, after exploring a maze, rats act as if they have learned a cognitive map of it.

cognitive neuroscience
the interdisciplinary study of the brain activity linked with cognition (perception, thinking, memory, and language).

cognitive psychology
the study of the mental processes involved in perceiving, learning, remembering, thinking, communicating, and solving problems.

cognitive therapy
therapy that teaches people new, more adaptive ways of thinking; based on the assumption that thoughts intervene between events and our emotional reactions.

cognitive-behavioral therapy (CBT)
a popular integrative therapy that combines cognitive therapy (changing self-defeating thinking) with behavior therapy (changing behavior).

cohort
a group of people sharing a common characteristic, such as being from a given time period.

collective unconscious
Carl Jung's concept of a shared, inherited reservoir of memory traces from our species' history.

collectivism

a cultural pattern that prioritizes the goals of important groups (often one's extended family or work group).

community psychology
a branch of psychology that studies how people interact with their social environments and how social institutions (such as schools and neighborhoods) affect individuals and groups.

companionate love
the deep affectionate attachment we feel for someone with whom our life is intertwined.

concept
a mental grouping of similar objects, events, ideas, or people.

concrete operational stage
in Piaget's theory, the stage of cognitive development (from about 7 to 11 years of age) at which children gain the mental operations that enable them to think logically about concrete events.

conditioned reinforcer
a stimulus that gains its reinforcing power through its association with a primary reinforcer. (Also known as a *secondary reinforcer.*)

conditioned response (CR)
in classical conditioning, a learned response to a previously neutral (but now conditioned) stimulus (CS).

conditioned stimulus (CS)
in classical conditioning, an originally neutral stimulus that, after association with an unconditioned stimulus (US), comes to trigger a conditioned response (CR).

conduction hearing loss

a less common form of hearing loss, caused by damage to the mechanical system that conducts sound waves to the cochlea.

cones
retinal receptors that are concentrated near the center of the retina and that function in daylight or in well-lit conditions. Cones detect fine detail and give rise to color sensations.

confirmation bias
a tendency to search for information that supports our preconceptions and to ignore or distort contradictory evidence.

conflict
a perceived incompatibility of actions, goals, or ideas.

conformity
adjusting our behavior or thinking to coincide with a group standard.

confounding variable
in an experiment, a variable other than the variable being studied that might influence a study's results.

consciousness
our subjective awareness of ourselves and our environment.

conservation
the principle (which Piaget believed to be a part of concrete operational reasoning) that properties such as mass, volume, and number remain the same despite changes in the forms of objects.

continuous reinforcement schedule
reinforcing the desired response every time it occurs.

control group

in an experiment, the group *not* exposed to the treatment; contrasts with the experimental group and serves as a comparison for evaluating the effect of the treatment.

convergent thinking
narrowing the available problem solutions to determine the single best solution.

coping
alleviating stress using emotional, cognitive, or behavioral methods.

coronary heart disease
the clogging of the vessels that nourish the heart muscle; a leading cause of death in many developed countries.

corpus callosum [KOR-pus kah-LOW-sum]
the large band of neural fibers connecting the two brain hemispheres and carrying messages between them.

correlation
a measure of the extent to which two factors vary together, and thus of how well either factor *(variable)* predicts the other.

correlation coefficient
a statistical index of the direction and strength of the relationship between two things (from −1.00 to +1.00).

counseling psychology
a branch of psychology that assists people with problems in living (often related to school, work, or relationships) and in achieving greater well-being.

counterconditioning
behavior therapy procedures that use classical conditioning to evoke new responses to stimuli that are triggering unwanted behaviors; include *exposure therapies* and *aversive conditioning*.

creativity
the ability to produce new and valuable ideas.

critical period
an optimal period early in the life of an organism when exposure to certain stimuli or experiences produces typical development.

critical thinking
thinking that does not automatically accept arguments and conclusions. Rather, it examines assumptions, appraises the source, discerns hidden biases, evaluates evidence, and assesses conclusions.

cross-sectional study
research that compares people of different ages at the same point in time.

crystallized intelligence *(Gc)*
our accumulated knowledge and verbal skills; tends to increase with age.

culture
the enduring behaviors, ideas, attitudes, values, and traditions shared by a group of people and transmitted from one generation to the next.

debriefing
the post experimental explanation of a study, including its purpose and any deceptions, to its participants.

deep processing
encoding semantically, based on the meaning of the words; tends to yield the best retention.

defense mechanisms
in psychoanalytic theory, the ego's protective methods of reducing anxiety by unconsciously distorting reality.

deindividuation
the loss of self-awareness and self-restraint occurring in group situations that foster arousal and anonymity.

déjà vu
that eerie sense that "I've experienced this before." Cues from the current situation may unconsciously trigger retrieval of an earlier experience.

delta waves
the large, slow brain waves associated with deep sleep.

delusion
a false belief, often of persecution or grandeur, that may accompany psychotic disorders.

dendrites
a neuron's often bushy, branching extensions that receive and integrate messages from axons, conducting impulses toward the cell body.

dependent variable
in an experiment, the variable that is measured; the variable that may change when the independent variable is manipulated.

depressants
drugs (such as alcohol, barbiturates, and opioids) that reduce neural activity and slow body functions.

depressive disorders
a group of disorders characterized by an enduring sad, empty, or irritable mood, along with physical and cognitive changes that affect a person's ability to function.

depth perception
the ability to see objects in three dimensions, although the images that strike the retina are two-dimensional; allows us to judge distance.

descriptive statistics
using statistical methods to provide a simple summary of data.

developmental psychology
a branch of psychology that studies physical, cognitive, and social development throughout the life span.

difference threshold
the minimum difference between two stimuli required for detection 50 percent of the time. We experience the difference threshold as a *just noticeable difference* (or *jnd*).

diffusion of responsibility
when a person takes less responsibility for something, or is less likely to act in a situation, due to the presence of others.

discrimination
(1) in classical conditioning, the learned ability to distinguish between a conditioned stimulus and similar stimuli that do not signal an unconditioned stimulus. (In operant conditioning, the ability to distinguish responses that are reinforced from similar responses that are not reinforced.) (2) unjustifiable negative behavior toward a group or its members.

dissociation
a split in consciousness, which allows some thoughts and behaviors to occur simultaneously with others.

dissociative disorders
a controversial, rare group of disorders characterized by a disruption of or discontinuity in the normal integration of consciousness, memory, identity, emotion, perception, body representation, motor control, and behavior.

dissociative identity disorder (DID)

a rare dissociative disorder in which a person exhibits two or more distinct and alternating identities. (Formerly called *multiple personality disorder.*)

divergent thinking
expanding the number of possible problem solutions; creative thinking that diverges in different directions.

DNA (deoxyribonucleic acid)
a complex molecule containing the genetic information that makes up the chromosomes.

double-blind procedure
an experimental procedure in which both the research participants and the research staff are uninformed (blind) about whether the research participants have received the treatment or a placebo. Commonly used in drug-evaluation studies.

dream
a sequence of images, emotions, and thoughts passing through a sleeping person's mind.

drive-reduction theory
the idea that a physiological need creates an aroused state (a drive) that motivates an organism to satisfy the need.

DSM–5–TR
the American Psychiatric Association's *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition, Text Revision;* a widely used categorical system for classifying psychological disorders.

dual processing
the principle that information is often simultaneously processed on separate conscious and unconscious tracks.

echoic memory
a momentary sensory memory of auditory stimuli; if attention is elsewhere, sounds and words can still be recalled within 3 or 4 seconds.

eclectic approach
an approach to psychotherapy that uses techniques from various forms of therapy.

Ecstasy (MDMA)
a synthetic stimulant and mild hallucinogen. Produces euphoria and social intimacy, but with short-term health risks and longer-term harm to serotonin-producing neurons and to mood and cognition.

EEG (electroencephalogram)
an amplified recording of the waves of electrical activity sweeping across the brain's surface. These waves are measured by electrodes placed on the scalp.

effortful processing
encoding that requires attention and conscious effort.

ego
the partly conscious, "executive" part of personality that, according to Freud, mediates among the demands of the id, the superego, and reality. The ego operates on the *reality principle,* satisfying the id's desires in ways that will realistically bring pleasure rather than pain.

egocentrism
in Piaget's theory, the preoperational child's difficulty taking another's point of view.

electroconvulsive therapy (ECT)
a biomedical therapy for severe and treatment-resistant depression in which a brief electric current is sent through the brain of an anesthetized person.

embodied cognition

the influence of bodily sensations, gestures, and other states on cognitive preferences and judgments.

embryo
the developing human organism from about 2 weeks after fertilization through the second month.

emerging adulthood
a period from about age 18 to the mid-twenties, when many in Western cultures are no longer adolescents but have not yet achieved full independence as adults.

emotion
a response of the whole organism, involving (1) physiological arousal, (2) expressive behaviors, and, most importantly, (3) conscious experience resulting from one's interpretations.

emotion regulation
how we manage our emotions, including which emotions we allow ourselves to feel, when we feel them, and how we express those emotions.

emotion-focused coping
attempting to alleviate stress by avoiding or ignoring a stressor and attending to emotional needs related to our stress reaction.

emotional intelligence
the ability to perceive, understand, manage, and use emotions.

empirical approach
an evidence-based method that draws on observation and experimentation.

empirically derived test
a test (such as the MMPI) created by selecting from a pool of items those that discriminate between groups.

encoding
the process of getting information into the memory system—for example, by extracting meaning.

encoding specificity principle
the idea that cues and contexts specific to a particular memory will be most effective in helping us recall it.

endocrine [EN-duh-krin] system
the body's "slow" chemical communication system; glands and fat tissue that secrete hormones into the bloodstream.

endorphins [en-DOR-fins]
"morphine within"—natural, opiate-like neurotransmitters linked to pain control and to pleasure.

environment
every nongenetic influence, from prenatal nutrition to the people and things around us.

epigenetics
"above" or "in addition to" *(epi)* genetics; the study of the molecular mechanisms by which environments can influence genetic expression (without a DNA change).

episodic memory
explicit memory of personally experienced events; one of our two conscious memory systems (the other is *semantic memory*).

equity
a condition in which people receive from a relationship in proportion to what they give to it.

erectile disorder

inability to develop or maintain an erection due to insufficient blood flow to the penis.

estrogens
sex hormones, such as estradiol, that contribute to female sex characteristics and are secreted in greater amounts by females than by males.

evidence-based practice
clinical decision making that integrates the best available research with clinical expertise and client characteristics and preferences.

evolutionary psychology
the study of the evolution of behavior and the mind, using principles of natural selection.

experiment
a research method in which an investigator manipulates one or more variables (independent variables) to observe the effect on some behavior or mental process (the dependent variable). By *random assignment* of participants, the experimenter aims to control other relevant variables that may change the research outcome.

experimental group
in an experiment, the group exposed to the treatment, that is, to one version of the independent variable.

explicit memory
retention of facts and experiences that we can consciously know and "declare." (Also called *declarative memory*.)

exposure therapies
behavioral techniques that treat anxieties by exposing people (in imaginary or actual situations) to the things they fear and avoid.

external locus of control

the perception that outside forces beyond our personal control determine our fate.

extinction
in classical conditioning, the diminishing of a conditioned response—when an unconditioned stimulus does not follow a conditioned stimulus. (In operant conditioning, when a response is no longer reinforced.)

extrasensory perception (ESP)
the controversial claim that perception can occur apart from sensory input; includes telepathy, clairvoyance, and precognition.

extrinsic motivation
the desire to perform a behavior to receive promised rewards or avoid threatened punishment.

facial feedback effect
the tendency of facial muscle activation, alone, to trigger corresponding feelings such as fear, anger, or happiness.

family therapy
therapy that treats people in the context of their family system. Views an individual's unwanted behaviors as influenced by, or directed at, other family members.

feature detectors
nerve cells in the brain's visual cortex that respond to specific features of the stimulus, such as shape, angle, or movement.

feel-good, do-good phenomenon
our tendency to be helpful when in a good mood.

female orgasmic disorder

distress due to weak orgasmic feelings or infrequently or never experiencing orgasm.

fetal alcohol syndrome (FAS)
physical and cognitive function deficits in children caused by their mother's heavy drinking during pregnancy. In severe cases, symptoms include a small, out-of-proportion head and distinct facial features.

fetus
the developing human organism from 9 weeks after conception to birth.

fight-or-flight response
an emergency response, including activation of the sympathetic nervous system, that mobilizes energy and activity for attacking or escaping a threat.

figure-ground
the organization of the visual field into objects (the *figures*) that stand out from their surroundings (the *ground*).

fixation
(1) in cognition, the inability to see a problem from a new perspective; an obstacle to problem solving. (2) in psychoanalytic theory, a lingering focus of pleasure-seeking energies at an earlier psychosexual stage, in which conflicts were unresolved.

fixed-interval schedule
in operant conditioning, a reinforcement schedule that reinforces a response only after a specified time has elapsed.

fixed-ratio schedule
in operant conditioning, a reinforcement schedule that reinforces a response only after a specified number of responses.

flashbulb memory

a clear memory of an emotionally significant moment or event.

flow
a completely involved, focused state, with diminished awareness of self and time; results from fully engaging our skills.

fluid intelligence *(Gf)*
our ability to reason speedily and abstractly; tends to decrease with age, especially during late adulthood.

fMRI (functional MRI)
a technique for revealing blood flow and, therefore, brain activity by comparing successive MRI scans. fMRI scans show brain function as well as structure.

foot-in-the-door phenomenon
the tendency for people who have first agreed to a small request to comply later with a larger request.

forebrain
consists of the cerebral cortex, thalamus, and hypothalamus; manages complex cognitive activities, sensory and associative functions, and voluntary motor activities.

formal operational stage
in Piaget's theory, the stage of cognitive development (usually beginning about age 12) at which people begin to think logically about abstract concepts.

fovea
the central focal point in the retina, around which the eye's cones cluster.

framing
the way an issue is posed; how an issue is framed can significantly affect decisions and judgments.

fraternal (dizygotic) twins
individuals who developed from separate fertilized eggs. They are genetically no closer than ordinary siblings, but shared a prenatal environment.

free association
in psychoanalysis, a method of exploring the unconscious in which the person relaxes and says whatever comes to mind, no matter how trivial or embarrassing.

frequency
the number of complete wavelengths that pass a point in a given time (for example, per second).

frequency theory
in hearing, the theory that the rate of nerve impulses traveling up the auditory nerve matches the frequency of a tone, thus enabling us to sense its pitch. (Also called *temporal coding*.)

frontal lobes
the portion of the cerebral cortex lying just behind the forehead; involved in speaking and muscle movements and in making plans and judgments.

frustration-aggression principle
the principle that frustration—the blocking of an attempt to achieve some goal—creates anger, which can generate aggression.

functionalism
an early school of thought promoted by James and influenced by Darwin; explored how mental and behavioral processes function—how they enable the organism to adapt, survive, and flourish.

fundamental attribution error
the tendency, when analyzing others' behavior, to underestimate the impact of the situation and to overestimate the impact of personal disposition.

gate-control theory
the theory that the spinal cord contains a neurological "gate" that blocks pain signals or allows them to pass on to the brain. The "gate" is opened by the activity of pain signals traveling up small nerve fibers and is closed by activity in larger fibers or by information coming from the brain.

gender
in psychology, the behavioral characteristics that people associate with *boy, girl, man,* and *woman.* (See also *gender identity.*)

gender identity
our personal sense of being male, female, neither, or some combination of male and female.

gender role
a set of expected behaviors, attitudes, and traits for men and for women.

gender typing
the acquisition of a traditional masculine or feminine role.

general adaptation syndrome (GAS)
Selye's concept of the body's adaptive response to stress in three phases—alarm, resistance, exhaustion.

general intelligence *(g)*
according to Spearman and others, underlies all mental abilities and is, therefore, measured by every task on an intelligence test.

generalization
(also called *stimulus generalization*) in classical conditioning, the tendency, once a response has been conditioned, for stimuli similar to the conditioned stimulus to elicit similar responses. (In operant conditioning, when responses learned in one situation occur in other, similar situations.)

generalized anxiety disorder
an anxiety disorder in which a person is continually tense, apprehensive, and in a state of autonomic nervous system arousal.

genes
the biochemical units of heredity that make up the chromosomes; small segments of DNA capable of synthesizing proteins.

genome
the complete instructions for making an organism, consisting of all the genetic material in that organism's chromosomes.

gestalt
an organized whole. Gestalt psychologists emphasized our tendency to integrate pieces of information into meaningful wholes.

glial cells (glia)
cells in the nervous system that support, nourish, and protect neurons; they also play a role in learning, thinking, and memory.

glucose
the form of sugar that circulates in the blood and provides the major source of energy for body tissues. When its level is low, we feel hunger.

grammar
in a language, a system of rules that enables us to communicate with and understand others. *Semantics* is the language's set of rules for deriving meaning from sounds, and *syntax* is its set of rules for combining words into grammatically sensible sentences.

GRIT
(1) in psychology, passion and perseverance in the pursuit of long-term goals. (2) Graduated and Reciprocated Initiatives in Tension-Reduction—a strategy designed to decrease international tensions.

group polarization
the enhancement of a group's prevailing inclinations through discussion within the group.

group therapy
therapy conducted with groups rather than individuals, providing benefits from group interaction.

grouping
the perceptual tendency to organize stimuli into coherent groups.

groupthink
the mode of thinking that occurs when the desire for harmony in a decision-making group overrides a realistic appraisal of alternatives.

growth mindset
a focus on learning and growing rather than viewing abilities as fixed.

gustation
our sense of taste.

habituation
decreasing responsiveness with repeated stimulation. As infants gain familiarity with repeated exposure to a stimulus, their interest wanes and they look away sooner.

hallucinations
sensory experiences without sensory stimulation, such as seeing something in the absence of an external visual stimulus.

hallucinogens
psychedelic ("mind-manifesting") drugs, such as LSD, that distort perceptions and evoke sensory images in the absence of sensory input.

happiness
an enduring prevalence of positive emotions.

health psychology
a subfield of psychology that contributes to behavioral medicine.

heredity
the genetic transfer of characteristics from parents to offspring.

heritability
the proportion of variation among individuals in a group that we can attribute to genes. The heritability of a trait may vary, depending on the range of populations and environments studied.

heuristic
a simple thinking strategy—a mental shortcut—that often allows us to make judgments and solve problems efficiently; usually speedier but also more error-prone than an *algorithm.*

hierarchy of needs
Maslow's five levels of human needs, beginning with physiological needs. Often visualized as a pyramid, with basic needs providing the foundation supporting higher-level needs.

higher-order conditioning
a procedure in which the conditioned stimulus in one conditioning experience is paired with a new neutral stimulus, creating a second (often weaker) conditioned stimulus. For example, an animal that has learned that a tone predicts food might then learn that a light predicts the tone and begin responding to the light alone. (Also called *second-order conditioning.*)

hindbrain
consists of the medulla, pons, and cerebellum; directs essential survival functions, such as breathing, sleeping, and wakefulness, as well as coordination

and balance.

hindsight bias
the tendency to believe, after learning an outcome, that one would have foreseen it. (Also known as the *I-knew-it-all-along phenomenon.*)

hippocampus
a neural center located in the limbic system that helps process explicit (conscious) memories—of facts and events—for storage.

homeostasis
a tendency to maintain a balanced or constant internal state; the regulation of any aspect of body chemistry, such as blood glucose, around a particular level.

hormones
chemical messengers that are manufactured by the endocrine glands, travel through the bloodstream, and affect other tissues.

hue
the dimension of color that is determined by the wavelength of light; what we know as the color names *blue, green,* and so forth.

human factors psychology
a field of psychology allied with I/O psychology that explores how people and machines interact and how machines and physical environments can be made safe and easy to use.

humanistic psychology
a historically significant perspective that emphasized human growth potential.

humanistic theories
theories that view personality with a focus on the potential for healthy personal growth.

hypnosis
a social interaction in which one person (the hypnotist) suggests to another (the subject) that certain perceptions, feelings, thoughts, or behaviors will spontaneously occur.

hypothalamus [hi-po-THAL-uh-muss]
a limbic system neural structure lying below *(hypo)* the thalamus; it directs several maintenance activities (eating, drinking, body temperature), helps govern the endocrine system via the pituitary gland, and is linked to emotion and reward.

hypothesis
a testable prediction, often implied by a theory.

iconic memory
a momentary sensory memory of visual stimuli; a photographic or picture-image memory lasting no more than a few tenths of a second.

id
a reservoir of unconscious psychic energy that, according to Freud, strives to satisfy basic sexual and aggressive drives. The id operates on the *pleasure principle,* demanding immediate gratification.

identical (monozygotic) twins
individuals who developed from a single fertilized egg that split in two, creating two genetically identical organisms.

identification
the process by which, according to Freud, children incorporate their parents' values into their developing superegos.

identity
our sense of self; according to Erikson, the adolescent's task is to solidify a sense of self by testing and integrating various roles.

illness anxiety disorder
a disorder in which a person interprets normal physical sensations as symptoms of a disease. (Formerly called *hypochondriasis*.)

illusory correlation
perceiving a relationship where none exists, or perceiving a stronger-than-actual relationship.

implicit bias
automatic associations that can influence individual judgments of or behavior toward people of a particular race, gender, or other group.

implicit memory
retention of learned skills or classically conditioned associations independent of conscious recollection. (Also called *nondeclarative memory*.)

imprinting
the process by which certain animals form strong attachments during early life.

inattentional blindness
failing to see visible objects when our attention is directed elsewhere.

incentive
a positive or negative environmental stimulus that motivates (or *pulls*) behavior.

independent variable
in an experiment, the variable that is manipulated; the variable whose effect is being studied.

individualism
a cultural pattern that emphasizes people's own goals over group goals and defines identity mainly in terms of unique personal attributes.

industrial-organizational (I/O) psychology

the scientific study of working, and the application of psychological concepts to human behavior in workplaces.

inferential statistics
using statistical methods to interpret data meaningfully.

informational social influence
influence resulting from a person's willingness to accept others' opinions about reality.

informed consent
giving potential participants enough information about a study to enable them to choose whether they wish to participate.

ingroup
"us"—people with whom we share a common identity.

ingroup bias
the tendency to favor our own group.

inner ear
the innermost part of the ear, containing the cochlea, semicircular canals, and vestibular sacs.

insight
a sudden realization of a problem's solution; contrasts with strategy-based solutions.

insight therapies
therapies that aim to improve psychological functioning by increasing a person's awareness of underlying motives and defenses.

insomnia
recurring problems in falling or staying asleep.

instinct
a complex behavior that is rigidly patterned throughout a species and is unlearned.

instinctive drift
the tendency of learned behavior to gradually revert to biologically predisposed patterns.

intellectual developmental disorder
a condition of limited mental ability, indicated by an intelligence test score of 70 or below and difficulty adapting to the demands of life. (May also be referred to as *intellectual disability*.)

intelligence
the ability to learn from experience, solve problems, and use knowledge to adapt to new situations.

intelligence quotient (IQ)
defined originally as the ratio of mental age *(ma)* to chronological age *(ca)* multiplied by 100 (thus, $\text{IQ} = ma/ca \times 100$). On contemporary intelligence tests, the average performance for a given age is assigned a score of 100.

intelligence test
a method for assessing an individual's mental aptitudes and comparing them with those of others, using numerical scores.

intensity
the amount of energy in a light wave or sound wave, which influences what those with typical vision or hearing perceive as brightness or loudness. Intensity is determined by the wave's amplitude (height).

interaction

the interplay that occurs when the effect of one factor (such as environment) depends on another factor (such as heredity).

internal locus of control
the perception that we control our own fate.

interneurons
neurons within the brain and spinal cord; they communicate internally and process information between the sensory inputs and motor outputs.

interpretation
in psychoanalysis, the analyst's noting of dream meanings, resistances, and other significant behaviors and events in order to promote insight and growth.

intersex
possessing male and female biological sexual characteristics at birth.

intimacy
in Erikson's theory, the ability to form close, loving relationships; a primary developmental task in young adulthood.

intrinsic motivation
a desire to perform a behavior effectively for its own sake.

intuition
an effortless, immediate, automatic feeling or thought, as contrasted with explicit, conscious reasoning.

James-Lange theory
the theory that our experience of emotion occurs when we become aware of our physiological responses to an emotion-arousing stimulus.

just-world phenomenon

the tendency for people to believe that the world is just and people therefore get what they deserve and deserve what they get.

kinesthesia [kin-ehs-THEE-zhuh]
our movement sense—our system for sensing the position and movement of individual body parts.

language
our spoken, written, or signed words and the ways we combine them to communicate meaning.

latent content
according to Freud, the underlying meaning of a dream (as distinct from its *manifest content*).

latent learning
learning that occurs but is not apparent until there is an incentive to demonstrate it.

law of effect
Thorndike's principle that behaviors followed by favorable consequences become more likely, and that behaviors followed by unfavorable consequences become less likely.

leadership
an individual's ability to motivate and influence others to contribute to their group's success.

learned helplessness
the hopelessness and passive resignation humans and other animals learn when unable to avoid repeated aversive events.

learning

the process of acquiring through experience new and relatively enduring information or behaviors.

lesion [LEE-zhuhn]
tissue destruction. Brain lesions occur naturally (disease or trauma), in surgery, or experimentally (using electrodes to destroy brain cells).

levels of analysis
the differing complementary views, from biological to psychological to social-cultural, for analyzing any given phenomenon.

limbic system
neural system located mostly in the forebrain—below the cerebral hemispheres—that includes the *amygdala, hypothalamus,* and *hippocampus;* associated with emotions and drives.

linguistic determinism
Whorf's hypothesis that language determines the way we think.

linguistic relativism
the idea that language influences the way we think.

lobotomy
a psychosurgical procedure once used to calm uncontrollably emotional or violent patients. The procedure cut the nerves that connect the frontal lobes to the emotion-controlling centers of the inner brain.

long-term memory
the relatively permanent and limitless archive of the memory system. Includes knowledge, skills, and experiences.

long-term potentiation (LTP)
an increase in a nerve cell's firing potential after brief, rapid stimulation; a neural basis for learning and memory.

longitudinal study
research that follows and retests the same people over time.

loose culture
places with flexible and informal norms.

LSD (lysergic acid diethylamide)
a powerful hallucinogenic drug; also known as *acid.*

magnetoencephalography (MEG)
a brain-imaging technique that measures magnetic fields from the brain's natural electrical activity.

major depressive disorder
a disorder in which a person experiences five or more symptoms lasting 2 or more weeks. In the absence of drug use or a medical condition, at least one symptom must be either (1) depressed mood or (2) loss of interest or pleasure.

mania
an unusually excited and overly ambitious mood state in which people show dangerously poor judgment, less need for sleep, and increased energy (part of bipolar disorders).

manifest content
according to Freud, the symbolic, remembered story line of a dream (as distinct from its *latent,* or hidden, content).

maturation
biological growth processes that enable orderly changes in behavior, relatively uninfluenced by experience.

mean
the arithmetic average of a distribution, obtained by adding the scores and then dividing by the number of scores.

median
the middle score in a distribution; half the scores are above it and half are below it.

medical model
the concept that diseases, in this case psychological disorders, have physical causes that can be *diagnosed, treated,* and, in most cases, *cured,* often through treatment in a *hospital.*

medulla [muh-DUL-uh]
the hindbrain structure that is the brainstem's base; controls heartbeat and breathing.

memory
the persistence of learning over time through the encoding, storage, and retrieval of information.

memory consolidation
the neural storage of a long-term memory.

menarche [meh-NAR-key]
the first menstrual period.

menopause
the time of natural cessation of menstruation; also refers to the biological changes a woman experiences as her ability to reproduce declines.

mental age
a measure of intelligence test performance devised by Binet; the level of performance typically associated with children of a certain chronological age. Thus, a child who does as well as an average 8-year-old is said to have a mental age of 8.

mental set

a tendency to approach a problem in one particular way, often a way that has been successful in the past.

mere exposure effect
the tendency for repeated exposure to novel stimuli to increase our liking of them.

meta-analysis
a statistical procedure for analyzing the results of multiple studies to reach an overall conclusion.

metacognition
cognition about our cognition; keeping track of and evaluating our mental processes.

methamphetamine
a powerfully addictive drug that stimulates the central nervous system, with accelerated body functions and associated energy and mood changes; over time, reduces baseline dopamine levels.

midbrain
found atop the brainstem; connects the *hindbrain* with the *forebrain,* controls some motor movement, and transmits auditory and visual information.

middle ear
the chamber between the eardrum and cochlea containing three tiny bones—hammer (malleus), anvil (incus), and stirrup (stapes)—that concentrate the vibrations of the eardrum on the cochlea's oval window.

mindfulness meditation
a reflective practice in which people attend to current experiences in a nonjudgmental and accepting manner.

Minnesota Multiphasic Personality Inventory (MMPI)

the most widely researched and clinically used of all personality tests. Originally developed to identify emotional disorders (still considered its most appropriate use), this test is now used for many other screening purposes.

mirror neurons
frontal lobe neurons that some scientists believe fire when we perform certain actions or observe another doing so. The brain's mirroring of another's action may enable imitation and empathy.

mirror-image perceptions
mutual views often held by conflicting parties, as when each side sees itself as ethical and peaceful and views the other side as evil and aggressive.

misinformation effect
occurs when a memory has been corrupted by misleading information.

mnemonics [nih-MON-iks]
memory aids, especially those techniques that use vivid imagery and organizational devices.

mode
the most frequently occurring score(s) in a distribution.

modeling
the process of observing and imitating a specific behavior.

molecular behavior genetics
the study of how the structure and function of genes interact with our environment to influence behavior.

molecular genetics
the subfield of biology that studies the molecular structure and function of genes.

monocular cue

a depth cue, such as interposition or linear perspective, available to either eye alone.

mood-congruent memory
the tendency to recall experiences that are consistent with one's current good or bad mood.

morpheme
in a language, the smallest unit that carries meaning; may be a word or a part of a word (such as a prefix).

motivation
a need or desire that energizes and directs (or *pushes*) behavior.

motor (efferent) neurons
neurons that carry outgoing information from the brain and spinal cord to the muscles and glands.

motor cortex
a cerebral cortex area at the rear of the frontal lobes that controls voluntary movements.

MRI (magnetic resonance imaging)
a technique that uses magnetic fields and radio waves to produce computer-generated images of soft tissue. MRI scans show brain anatomy.

mutation
a random error in gene replication that leads to a change.

myelin [MY-uh-lin] sheath
a fatty tissue layer segmentally encasing the axons of some neurons; enables vastly greater transmission speed as neural impulses hop from one node to the next.

narcissism
excessive self-love and self-absorption.

narcolepsy
a sleep disorder characterized by uncontrollable sleep attacks. The sufferer may lapse directly into REM sleep, often at inopportune times.

natural selection
the principle that inherited traits that better enable an organism to survive and reproduce in a particular environment will (in competition with other trait variations) most likely be passed on to succeeding generations.

naturalistic observation
a descriptive technique of observing and recording behavior in naturally occurring situations without changing or controlling the situation.

nature–nurture issue
the longstanding controversy over the relative contributions that genes and experience make to the development of psychological traits and behaviors. Today's science sees traits and behaviors arising from the interaction of nature and nurture.

near-death experience
an altered state of consciousness reported after a close brush with death (such as cardiac arrest); often similar to drug-induced hallucinations.

negative punishment
an event that decreases behavior by removing a rewarding stimulus.

negative reinforcement
increasing behaviors by stopping or reducing an aversive stimulus. A negative reinforcer is any stimulus that, when *removed* after a response, strengthens the response. (*Note:* Negative reinforcement is not punishment.)

nerves
bundled axons that form neural cables connecting the central nervous system with muscles, glands, and sensory organs.

nervous system
the body's speedy, electrochemical communication network, consisting of all the nerve cells of the peripheral and central nervous systems.

neurocognitive disorders (NCDs)
acquired (not lifelong) disorders marked by cognitive deficits; often related to Alzheimer's disease, brain injury or disease, or substance abuse. Also called *dementia* in older adults.

neurodevelopmental disorder
central nervous system developmental differences (usually in the brain) that start in childhood and alter thinking and behavior (as in intellectual limitations or a psychological disorder).

neurogenesis
the formation of new neurons.

neuron
a nerve cell; the basic building block of the nervous system.

neuroplasticity
the brain's ability to change, especially during childhood, by reorganizing after damage or by building new pathways based on experience.

neurotransmitters
chemical messengers that cross the synaptic gap between neurons. When released by the sending neuron, neurotransmitters travel across the synapse and bind to receptor sites on the receiving neuron, thereby influencing whether that neuron will generate a neural impulse.

neutral stimulus (NS)
in classical conditioning, a stimulus that elicits no response before conditioning.

nicotine
a stimulating and highly addictive psychoactive drug in tobacco products.

night terrors
a sleep disorder characterized by high arousal and an appearance of being terrified; unlike nightmares, night terrors occur during N3 sleep, within 2 or 3 hours of falling asleep, and are seldom remembered.

normal curve
a symmetrical, bell-shaped curve that describes the distribution of many types of data; most scores fall near the mean (about 68 percent fall within one standard deviation of it) and fewer and fewer near the extremes. (Also called a *normal distribution.*)

normative social influence
influence resulting from a person's desire to gain approval or avoid disapproval.

norms
understood rules for accepted and expected behavior. Norms prescribe "proper" behavior.

nudge
framing choices in a way that encourages people to make beneficial decisions.

obesity
defined as a body mass index (BMI) measurement of 30 or higher, which is calculated from our weight-to-height ratio. (Individuals who are *overweight* have a BMI of 25 or higher.)

object permanence
the awareness that things continue to exist even when not perceived.

observational learning
learning by observing others. (Also called *social learning*.)

obsessive-compulsive disorder (OCD)
a disorder characterized by unwanted and repetitive thoughts (obsessions), actions (compulsions), or both.

occipital [ahk-SIP-uh-tuhl] lobes
the portion of the cerebral cortex lying at the back of the head; includes areas that receive information from the visual fields.

Oedipus [ED-uh-puss] complex
according to Freud, a boy's sexual desires toward his mother and feelings of jealousy and hatred for the rival father.

olfaction
our sense of smell.

one-word stage
the stage in speech development, from about age 1 to 2, during which a child speaks mostly in single words.

operant behavior
behavior that operates on the environment, producing a consequence.

operant chamber
in operant conditioning research, a chamber (also known as a *Skinner box*) containing a bar or key that an animal can manipulate to obtain a food or water reinforcer; attached devices record the animal's rate of bar pressing or key pecking.

operant conditioning
a type of learning in which a behavior becomes more likely to recur if followed by a reinforcer or less likely to recur if followed by a punisher.

operational definition
a carefully worded statement of the exact procedures (operations) used in a research study. For example, *human intelligence* may be operationally defined as what an intelligence test measures. (Also known as *operationalization.*)

opioids
opium and its derivatives, such as morphine and heroin; depress neural activity, temporarily lessening pain and anxiety.

opponent-process theory
the theory that opposing retinal processes (red-green, blue-yellow, white-black) enable color vision. For example, some cells are stimulated by green and inhibited by red; others are stimulated by red and inhibited by green.

optic nerve
the nerve that carries neural impulses from the eye to the brain.

organizational psychology
an I/O psychology subfield that examines organizational influences on worker satisfaction and productivity and facilitates organizational change.

ostracism
deliberate social exclusion of individuals or groups.

other-race effect
the tendency to recall faces of one's own race more accurately than faces of other races. Also called the *cross-race effect* and the *own-race bias*.

outgroup
"them"—those perceived as different or apart from our ingroup.

overconfidence
the tendency to be more confident than correct—to overestimate the accuracy of our beliefs and judgments.

panic disorder
an anxiety disorder marked by unpredictable, minutes-long episodes of intense dread in which a person may experience terror and accompanying chest pain, choking, or other frightening sensations; often followed by worry over a possible next attack.

parallel processing
processing multiple aspects of a stimulus or problem simultaneously.

paraphilias
sexual arousal from fantasies, behaviors, or urges involving nonhuman objects, the suffering of self or others, and/or nonconsenting persons.

parapsychology
the study of paranormal phenomena, including ESP and psychokinesis (also called *telekinesis*).

parasympathetic nervous system
the division of the autonomic nervous system that calms the body, conserving its energy.

parietal [puh-RYE-uh-tuhl] lobes
the portion of the cerebral cortex lying at the top of the head and toward the rear; receives sensory input for touch and body position.

partial (intermittent) reinforcement schedule
reinforcing a response only part of the time; results in slower acquisition of a response but much greater resistance to extinction than does continuous reinforcement.

passionate love
an aroused state of intense positive absorption in another, usually present at the beginning of a romantic relationship.

peer reviewers
scientific experts who evaluate a research article's theory, originality, and accuracy.

perception
the process by which our brain organizes and interprets sensory information, enabling us to recognize objects and events as meaningful.

perceptual adaptation
the ability to adjust to changed sensory input, including an artificially displaced or even inverted visual field.

perceptual constancy
perceiving objects as unchanging (having consistent color, brightness, shape, and size) even as illumination and retinal images change.

perceptual set
a mental predisposition to perceive one thing and not another.

peripheral nervous system (PNS)
the sensory and motor neurons that connect the central nervous system (CNS) to the rest of the body.

peripheral route persuasion
occurs when people are influenced by attention-getting cues, such as a speaker's attractiveness.

person-centered therapy
a humanistic therapy, developed by Carl Rogers, in which the client directs the discussion and the therapist uses techniques such as *active listening* within an accepting, genuine, empathic environment to facilitate clients' growth. (Also called *client-centered therapy*.)

personal control

our sense of being in charge of our environment rather than feeling helpless.

personality
an individual's characteristic pattern of thinking, feeling, and acting.

personality disorders
a group of disorders characterized by enduring inner experiences or behavior patterns that differ from the person's cultural norms and expectations, are pervasive and inflexible, begin in adolescence or early adulthood, are stable over time, and cause distress or impairment.

personality inventory
a questionnaire (often with *true-false* or *agree-disagree* items) on which people respond to items designed to gauge a wide range of feelings and behaviors; used to assess selected personality traits.

personnel psychology
an I/O psychology subfield that helps with job seeking, and with employee recruitment, selection, placement, training, appraisal, and development.

PET (positron emission tomography)
a technique for detecting brain activity that displays where a radioactive form of glucose goes while the brain performs a given task.

phi phenomenon
an illusion of movement created when two or more adjacent lights blink on and off in quick succession.

phoneme
in a language, the smallest distinctive sound unit.

physiological need
a basic bodily requirement.

pitch
a tone's experienced highness or lowness; depends on frequency.

pituitary gland
the endocrine system's most influential gland. Under the influence of the hypothalamus, the pituitary regulates growth and controls other endocrine glands.

place theory
in hearing, the theory that links the pitch we hear with the place where the cochlea's membrane is stimulated. (Also called *place coding*.)

placebo [pluh-SEE-bo; Latin for "I shall please"] effect
experimental results caused by expectations alone; any effect on behavior caused by the administration of an inert substance or condition, which the recipient assumes is an active agent.

polygraph
a machine used in attempts to detect lies; measures emotion-linked changes in perspiration, heart rate, and breathing.

population
all those in a group being studied, from which random samples may be drawn. (*Note:* Except for national studies, this does *not* refer to a country's whole population.)

positive psychology
the scientific study of human flourishing, with the goals of discovering and promoting strengths and virtues that help individuals and communities to thrive.

positive punishment
an event that decreases a behavior by administering a negative stimulus.

positive reinforcement

increasing behaviors by presenting a pleasurable stimulus. A positive reinforcer is any stimulus that, when *presented* after a response, strengthens the response.

posthypnotic suggestion
a suggestion, made during a hypnosis session, to be carried out after the subject is no longer hypnotized; used by some clinicians to help control undesired symptoms and behaviors.

posttraumatic growth
positive psychological changes following a struggle with extremely challenging circumstances and life crises.

posttraumatic stress disorder (PTSD)
a disorder characterized by haunting memories, nightmares, hypervigilance, avoidance of trauma-related stimuli, social withdrawal, jumpy anxiety, numbness of feeling, and/or insomnia that lingers for 4 weeks or more after a traumatic experience.

predictive validity
the success with which a test predicts the behavior it is designed to predict; it is assessed by computing the correlation between test scores and the criterion behavior. (Also called *criterion-related validity.*)

prejudice
an unjustifiable and usually negative attitude toward a group and its members. Prejudice generally involves stereotyped beliefs, negative feelings, and a predisposition to discriminatory action.

preoperational stage
in Piaget's theory, the stage (from about 2 to 6 or 7 years of age) at which a child learns to use language but does not yet comprehend the mental operations of concrete logic.

preparedness

a biological predisposition to learn associations, such as between taste and nausea, that have survival value.

preregistration
publicly communicating planned study design, hypotheses, data collection, and analyses.

primary reinforcer
an innately reinforcing stimulus, such as one that satisfies a biological need.

primary sex characteristics
the body structures (ovaries, testes, and external genitalia) that make sexual reproduction possible.

priming
the activation, often unconsciously, of certain associations, thus predisposing one's perception, memory, or response.

proactive interference
the forward-acting disruptive effect of older learning on the recall of *new* information.

problem-focused coping
attempting to alleviate stress directly—by changing the stressor or the way we interact with that stressor.

projective test
a personality test, such as the TAT or Rorschach, that provides ambiguous images designed to trigger projection of people's inner dynamics.

prosocial behavior
positive, constructive, helpful behavior. The opposite of antisocial behavior.

prototype

a mental image or best example of a category. Matching new items to a prototype provides a quick and easy method for sorting items into categories (as when comparing feathered creatures to a prototypical bird, such as a crow).

psychedelic drugs
hallucinogenic drugs used to treat depressive disorders, anxiety disorders, posttraumatic stress disorder, and substance use disorders. These drugs cause temporary visual, psychological, and auditory changes, and an altered state of consciousness (often called a psychedelic experience or "trip").

psychiatry
a branch of medicine dealing with psychological disorders; practiced by physicians who provide medical (for example, drug) treatments as well as psychological therapy.

psychoactive drug
a chemical substance that alters the brain, causing changes in perceptions and moods.

psychoanalysis
(1) Freud's theory of personality that attributes thoughts and actions to unconscious motives and conflicts. (2) Freud's therapeutic technique. Freud believed the patient's free associations, resistances, and dreams—and the analyst's interpretations of them—released previously repressed feelings, allowing the patient to gain self-insight.

psychodynamic theories
theories that view personality with a focus on the unconscious mind and the importance of childhood experiences.

psychodynamic therapy
therapy deriving from the psychoanalytic tradition; views individuals as responding to unconscious forces and childhood experiences, and seeks to

enhance self-insight.

psychological disorder
a disturbance in people's thoughts, emotions, or behaviors that causes distress or suffering and impairs their daily lives.

psychology
the science of behavior and mental processes.

psychoneuroimmunology
the study of how psychological, neural, and endocrine processes together affect our immune system and resulting health.

psychopharmacology
the study of the effects of drugs on the mind and behavior.

psychophysics
the study of relationships between the physical characteristics of stimuli, such as their intensity, and our psychological experience of them.

psychosexual stages
the childhood stages of development (oral, anal, phallic, latency, genital) during which, according to Freud, the id's pleasure-seeking energies focus on distinct *erogenous zones.*

psychosurgery
surgery that removes or destroys brain tissue to change behavior.

psychotherapy
treatment involving psychological techniques; consists of interactions between a trained therapist and someone seeking to address psychological difficulties or achieve personal growth.

psychotic disorders

a group of disorders marked by irrational ideas, distorted perceptions, and a loss of contact with reality.

puberty
the period of sexual maturation, during which a person usually becomes capable of reproducing.

random assignment
assigning participants to experimental and control groups by chance, thus minimizing preexisting differences between the different groups.

random sample
a sample that fairly represents a population because each member has an equal chance of inclusion.

range
the difference between the highest and lowest scores in a distribution.

recall
a measure of memory in which the person must retrieve information learned earlier, as on a fill-in-the-blank test.

reciprocal determinism
the interacting influences of behavior, internal cognition, and environment.

reciprocity norm
an expectation that people will help, not hurt, those who have helped them.

recognition
a measure of memory in which the person identifies items previously learned, as on a multiple-choice test.

reconsolidation

a process in which previously stored memories, when retrieved, are potentially altered before being stored again.

reflex
a simple, automatic response to a sensory stimulus, such as the knee-jerk reflex.

refractory period
(1) in neural processing, a brief resting pause that occurs after a neuron has fired; subsequent action potentials cannot occur until the axon returns to its resting state. (2) in human sexuality, a resting period that occurs after orgasm, during which a person cannot achieve another orgasm.

regression toward the mean
the tendency for extreme or unusual scores or events to fall back (regress) toward the average.

reinforcement
in operant conditioning, any event that *strengthens* the behavior it follows.

reinforcement schedule
a pattern that defines how often a desired response will be reinforced.

relational aggression
an act of aggression (physical or verbal) intended to harm a person's relationship or social standing.

relative deprivation
the perception that we are worse off relative to those with whom we compare ourselves.

relearning
a measure of memory that assesses the amount of time saved when learning material again.

reliability
the extent to which a test yields consistent results, as assessed by the consistency of scores on two halves of the test, on alternative forms of the test, or on retesting.

REM rebound
the tendency for REM sleep to increase following REM sleep deprivation.

REM sleep
rapid eye movement sleep; a recurring sleep stage during which vivid dreams commonly occur. Also known as *paradoxical sleep,* because the muscles are relaxed (except for minor twitches) but other body and brain systems are active. (Sometimes called *R sleep.*)

REM sleep behavior disorder
a sleep disorder characterized by acting out dreams while sleeping, through physical movements (such as kicking or striking out) and vocal behaviors (such as talking or yelling).

replication
repeating the essence of a research study, usually with different participants in different situations, to see whether the basic finding can be reproduced.

representativeness heuristic
judging the likelihood of events in terms of how well they seem to represent, or match, particular prototypes; may lead us to ignore other relevant information.

repression
in psychoanalytic theory, the basic defense mechanism that banishes from consciousness anxiety-arousing thoughts, feelings, and memories.

resilience
the personal strength that helps people cope with stress and recover from adversity and even trauma.

resistance
in psychoanalysis, the blocking from consciousness of unpleasant or anxiety-laden material.

respondent behavior
behavior that occurs as an automatic response to some stimulus.

reticular formation
a nerve network that travels through the brainstem into the thalamus; filters information and plays an important role in controlling arousal.

retina
the light-sensitive back inner surface of the eye, containing the receptor rods and cones plus layers of neurons that begin the processing of visual information.

retinal disparity
a binocular cue for perceiving depth. By comparing retinal images from the two eyes, the brain computes distance—the greater the disparity (difference) between the two images, the closer the object.

retrieval
the process of getting information out of memory storage.

retroactive interference
the backward-acting disruptive effect of newer learning on the recall of *old* information.

retrograde amnesia
an inability to remember information from one's past.

reuptake
a neurotransmitter's reabsorption by the sending neuron.

rods

retinal receptors that detect black, white, and gray, and are sensitive to movement. Rods are necessary for peripheral and twilight vision, when cones don't respond.

role
a set of expectations *(norms)* about a social position, defining how those in the position ought to behave.

Rorschach inkblot test
a projective test designed by Hermann Rorschach; seeks to identify people's inner feelings by analyzing how they interpret 10 inkblots.

rumination
compulsive fretting; *overthinking* our problems and their causes.

savant syndrome
a condition in which a person otherwise limited in mental ability has an exceptional specific skill, such as in computation or drawing.

scaffold
in Vygotsky's theory, a framework that offers children temporary support as they develop higher levels of thinking.

scapegoat theory
the theory that prejudice offers an outlet for anger by providing someone to blame.

scatterplot
a graphed cluster of dots, each of which represents the values of two variables. The slope of the points suggests the direction of the relationship between the two variables. The amount of scatter suggests the strength of the correlation (little scatter indicates high correlation).

schema

a concept or framework that organizes and interprets information.

schizophrenia
a disorder characterized by delusions, hallucinations, disorganized speech, and/or diminished, inappropriate emotional expression.

secondary sex characteristics
nonreproductive sexual traits, such as female breasts and hips, male voice quality, and body hair.

selective attention
focusing conscious awareness on a particular stimulus.

self
in contemporary psychology, assumed to be the center of personality, the organizer of our thoughts, feelings, and actions.

self-actualization
according to Maslow, one of the ultimate psychological needs that arises after basic physical and psychological needs are met and self-esteem is achieved; the motivation to fulfill one's potential.

self-concept
all our thoughts and feelings about ourselves, in answer to the question, "Who am I?"

self-control
the ability to control impulses and delay short-term gratification for greater long-term rewards.

self-determination theory
the theory that we feel motivated to satisfy our needs for competence, autonomy, and relatedness.

self-disclosure
the act of revealing intimate aspects of ourselves to others.

self-efficacy
our sense of competence and effectiveness.

self-esteem
our feelings of high or low self-worth.

self-fulfilling prophecy
a belief that leads to its own fulfillment.

self-report
a method of recording participants' descriptions of their personality traits, often using surveys, questionnaires, or tests.

self-serving bias
a readiness to perceive ourselves favorably.

self-transcendence
according to Maslow, the striving for identity, meaning, and purpose beyond the self.

semantic memory
explicit memory of facts and general knowledge; one of our two conscious memory systems (the other is *episodic memory*).

sensation
the process by which our sensory receptors and nervous system receive and represent stimulus energies from our environment.

sensorimotor stage
in Piaget's theory, the stage (from birth to nearly 2 years of age) at which infants know the world mostly in terms of their sensory impressions and motor activities.

sensorineural hearing loss
the most common form of hearing loss, caused by damage to the cochlea's receptor cells or to the auditory nerve; also called *nerve deafness*.

sensory (afferent) neurons
neurons that carry incoming information from the body's tissues and sensory receptors to the brain and spinal cord.

sensory adaptation
diminished sensitivity as a consequence of constant stimulation.

sensory interaction
the principle that one sense can influence another, as when the smell of food influences its taste.

sensory memory
the immediate, very brief recording of sensory information in the memory system.

sensory receptors
sensory nerve endings that respond to stimuli.

sequential processing
processing one aspect of a stimulus or problem at a time; generally used to process new information or to solve difficult problems.

serial position effect
our tendency to recall best the last *(recency effect)* and first *(primacy effect)* items in a list.

set point
the point at which the "weight thermostat" may be set. When the body falls below this weight, increased hunger and a lowered metabolic rate may combine to restore lost weight.

sex
in psychology, the biologically influenced characteristics by which people define *male, female,* and *intersex.*

sexual aggression
any physical or verbal behavior of a sexual nature that is unwanted or intended to harm someone physically or emotionally. Can be expressed as either *sexual harassment* or *sexual assault.*

sexual dysfunction
a problem that consistently impairs sexual arousal or functioning at any point in the sexual response cycle.

sexual orientation
the direction of our sexual attractions, as reflected in our longings and fantasies.

sexual response cycle
the four stages of sexual responding described by Masters and Johnson—excitement, plateau, orgasm, and resolution.

sexuality
our thoughts, feelings, and actions related to our physical attraction to another.

shallow processing
encoding on a basic level, based on the structure or appearance of words.

shaping
an operant conditioning procedure in which reinforcers guide behavior toward closer and closer approximations of the desired behavior.

short-term memory
briefly activated memory of a few items (such as digits of a phone number while calling) that is later stored or forgotten.

signal detection theory
a theory predicting how and when we detect the presence of a faint stimulus *(signal)* amid background stimulation *(noise)*. Assumes there is no single absolute threshold and that detection depends partly on a person's experience, expectations, motivation, and alertness.

sleep
a periodic, natural loss of consciousness—as distinct from unconsciousness resulting from a coma, general anesthesia, or hibernation. (Information from Dement, 1999.)

sleep apnea
a sleep disorder characterized by temporary cessations of breathing during sleep and repeated momentary awakenings.

social anxiety disorder
intense fear and avoidance of social situations.

social clock
the culturally preferred timing of social events such as marriage, parenthood, and retirement.

social exchange theory
the theory that our social behavior is an exchange process, the aim of which is to maximize benefits and minimize costs.

social facilitation
in the presence of others, improved performance on simple or well-learned tasks, and worsened performance on difficult tasks.

social identity
the "we" aspect of our self-concept; the part of our answer to "Who am I?" that comes from our group memberships.

social leadership
group-oriented leadership that builds teamwork, mediates conflict, and offers support.

social learning theory
the theory that we learn social behavior by observing and imitating and by being rewarded or punished.

social loafing
the tendency for people in a group to exert less effort when pooling their efforts toward attaining a common goal than when individually accountable.

social psychology
the scientific study of how we think about, influence, and relate to one another.

social script
a culturally modeled guide for how to act in various situations.

social trap
a situation in which two parties, by each pursuing their self-interest rather than the good of the group, become caught in mutually destructive behavior.

social-cognitive perspective
a view of behavior as influenced by the interaction between people's traits (including their thinking) and their social context.

social-responsibility norm
an expectation that people will help those needing their help.

somatic nervous system
the division of the peripheral nervous system that controls the body's skeletal muscles. Also called the *skeletal nervous system.*

somatic symptom disorder

a psychological disorder in which the symptoms take a somatic (bodily) form without apparent physical cause.

somatosensory cortex
a cerebral cortex area at the front of the parietal lobes that registers and processes body touch and movement sensations.

source amnesia
faulty memory for how, when, or where information was learned or imagined. (Also called *source misattribution.*) Source amnesia, along with the misinformation effect, is at the heart of many false memories.

spacing effect
the tendency for distributed study or practice to yield better long-term retention than is achieved through massed study or practice.

specific phobia
an anxiety disorder marked by a persistent, irrational fear and avoidance of a specific object, activity, or situation.

spermarche [sper-MAR-key]
the first ejaculation.

split brain
a condition resulting from surgery that separates the brain's two hemispheres by cutting the fibers (mainly those of the corpus callosum) connecting them.

spontaneous recovery
the reappearance, after a pause, of a weakened conditioned response.

spotlight effect
overestimating others' noticing and evaluating our appearance, performance, and blunders (as if we presume a spotlight shines on us).

SQ3R
a study method incorporating five steps: *S*urvey, *Q*uestion, *R*ead, *R*etrieve, *R*eview.

standard deviation
a computed measure of how much scores vary around the mean score.

standardization
defining uniform testing procedures and meaningful scores by comparison with the performance of a pretested group.

Stanford-Binet
the widely used U.S. revision (by Terman at Stanford University) of Binet's original intelligence test.

statistical significance
a statistical statement of how likely it is that an obtained result (such as a difference between samples) occurred by chance, assuming there is no difference between the populations being studied.

statistics
using mathematical methods to understand numerical information *(data)*.

stereotype
a generalized (sometimes accurate but often overgeneralized) belief about a group of people.

stereotype threat
a self-confirming concern that one will be evaluated based on a negative stereotype.

stimulants
drugs (such as caffeine, nicotine, and the more powerful cocaine, amphetamines, methamphetamine, and Ecstasy) that excite neural activity and speed up body functions.

stimulus
any event or situation that evokes a response.

storage
the process of retaining encoded information over time.

stranger anxiety
the fear of strangers that infants commonly display, beginning by about 8 months of age.

stress
the process by which we perceive and respond to certain events, called *stressors,* that we appraise as threatening or challenging.

structuralism
an early school of thought promoted by Wundt and Titchener; used introspection to reveal the structure of the human mind.

structured interviews
an interview process that asks the same job-relevant questions of all applicants, each of whom is rated on established scales.

subjective well-being
self-perceived satisfaction with life. Used along with measures of objective well-being (for example, physical and economic indicators) to judge our quality of life.

subliminal stimulation
presenting something below one's absolute threshold for conscious awareness.

substance use disorder
a disorder characterized by continued substance use despite significant life disruption.

superego

the partly conscious part of personality that, according to Freud, represents internalized ideals and provides standards for judgment (the conscience) and for future aspirations.

superordinate goals
shared goals that override differences among people and require their cooperation.

suprachiasmatic nucleus (SCN)
a pair of cell clusters in the hypothalamus that controls circadian rhythm. In response to light, the SCN causes the pineal gland to adjust melatonin production, thus modifying our feelings of sleepiness.

survey
a descriptive technique for obtaining the self-reported attitudes or behaviors of a particular group, usually by questioning a representative, *random sample* of the group.

sympathetic nervous system
the division of the autonomic nervous system that arouses the body, mobilizing its energy.

synapse [SIN-aps]
the junction between the axon tip of the sending neuron and the dendrite or cell body of the receiving neuron. The tiny gap at this junction is called the *synaptic gap* (or *synaptic cleft*).

syntax
the correct way to string words together to form sentences for a given language.

systematic desensitization
a type of exposure therapy that associates a pleasant relaxed state with gradually increasing anxiety-triggering stimuli. Commonly used to treat specific phobias.

task leadership
goal-oriented leadership that sets standards, organizes work, and focuses attention on goals.

telegraphic speech
the early speech stage in which a child speaks like a telegram—"go car"—using mostly nouns and verbs.

temperament
a person's characteristic emotional reactivity and intensity.

temporal lobes
the portion of the cerebral cortex lying roughly above the ears; includes the auditory areas, each receiving information primarily from the opposite ear.

tend-and-befriend response
under stress, people (especially women) often provide support to others *(tend)* and bond with and seek support from others *(befriend).*

teratogens
agents, such as chemicals and viruses, that can reach the embryo or fetus during prenatal development and cause harm.

terror-management theory
a theory of death-related anxiety; explores people's emotional and behavioral responses to reminders of their impending death.

testing effect
enhanced memory after retrieving, rather than simply rereading, information. Also referred to as a *retrieval practice effect* or *test-enhanced learning.*

testosterone
the most important male sex hormone. Males and females have it, but the additional testosterone in males stimulates the growth of the male sex organs

during the fetal period, and the development of the male sex characteristics during puberty.

thalamus [THAL-uh-muss]
the forebrain's sensory control center, located on top of the brainstem; it directs messages to the sensory receiving areas in the cortex and transmits replies to the cerebellum and medulla.

THC (delta-9-tetrahydrocannabinol)
the major mind-altering ingredient in marijuana.

Thematic Apperception Test (TAT)
a projective test in which people express their inner feelings and interests through the stories they make up about ambiguous scenes.

theory
an explanation using an integrated set of principles that organizes observations and predicts behaviors or events.

theory of mind
people's ideas about their own and others' mental states—about their feelings, perceptions, and thoughts, and the behaviors these might predict.

therapeutic alliance
a bond of trust and mutual understanding between a therapist and client, who work together constructively to overcome the client's problem.

threshold
the level of stimulation required to trigger a neural impulse.

tight culture
places with clearly defined and reliably imposed norms.

token economy

an operant conditioning procedure in which people earn a token for exhibiting a desired behavior and can later exchange tokens for privileges or treats.

tolerance
the diminishing effect with regular use of the same dose of a drug, requiring the user to take larger and larger doses before experiencing the drug's effect.

top-down processing
information processing guided by higher-level mental processes, as when we construct perceptions drawing on our experience and expectations.

trait
a characteristic pattern of behavior or a disposition to feel and act in certain ways, as assessed by self-report inventories and peer reports.

transcranial magnetic stimulation (TMS)
the application of repeated pulses of magnetic energy to the brain; used to stimulate or suppress brain activity.

transduction
conversion of one form of energy into another. In sensation, the transforming of physical energy, such as sights, sounds, and smells, into neural impulses our brain can interpret.

transference
in psychoanalysis, the patient's transfer to the analyst of emotions linked with other relationships (such as love or hatred for a parent).

transgender
an umbrella term describing people whose gender identity differs from that associated with their sex assigned at birth.

trauma- and stressor-related disorders

a group of disorders in which exposure to a traumatic or stressful event is followed by psychological distress.

two-factor theory
the Schachter-Singer theory that to experience emotion one must (1) be physically aroused and (2) cognitively label the arousal.

two-word stage
the stage in speech development, beginning about age 2, during which a child speaks mostly in two-word sentences.

Type A
Friedman and Rosenman's term for competitive, hard-driving, impatient, verbally aggressive, and anger-prone people.

Type B
Friedman and Rosenman's term for easygoing, relaxed people.

unconditional positive regard
a caring, accepting, and nonjudgmental attitude, which Carl Rogers believed would help clients develop self-awareness and self-acceptance.

unconditioned response (UR)
in classical conditioning, an unlearned, naturally occurring response (such as salivation) to an unconditioned stimulus (US) (such as food in the mouth).

unconditioned stimulus (US)
in classical conditioning, a stimulus that unconditionally—naturally and automatically—triggers an unconditioned response (UR).

unconscious
according to Freud, a reservoir of mostly unacceptable thoughts, wishes, feelings, and memories. According to contemporary psychologists, information processing of which we are unaware.

validity
the extent to which a test measures or predicts what it is supposed to. (See also *predictive validity.*)

variable
anything that can vary and is practical and ethical to measure.

variable-interval schedule
in operant conditioning, a reinforcement schedule that reinforces a response at unpredictable time intervals.

variable-ratio schedule
in operant conditioning, a reinforcement schedule that reinforces a response after an unpredictable number of responses.

vestibular sense
our balance sense—our sense of body movement and position that enables our sense of balance.

virtual reality exposure therapy
a counterconditioning technique that treats anxiety through creative electronic simulations in which people can safely face specific fears, such as flying, spiders, or public speaking.

visual cliff
a laboratory device for testing depth perception in infants and young animals.

wavelength
the distance from the peak of one light or sound wave to the peak of the next. Electromagnetic wavelengths vary from the short blips of gamma rays to the long pulses of radio transmission.

Weber's law

the principle that, to be perceived as different, two stimuli must differ by a constant minimum percentage (rather than a constant amount).

Wechsler Adult Intelligence Scale (WAIS)
the WAIS and its companion versions for children are the most widely used intelligence tests; they contain verbal and performance (nonverbal) subtests.

Wernicke's area
a brain area, usually in the left temporal lobe, involved in language comprehension and expression.

withdrawal
the discomfort and distress that follow discontinuing an addictive drug or behavior.

working memory
a newer understanding of short-term memory; conscious, active processing of both (1) incoming sensory information and (2) information retrieved from long-term memory.

X chromosome
the sex chromosome found in females and males. Females typically have two X chromosomes; males typically have one. An X chromosome from each parent produces a female child.

Y chromosome
the sex chromosome typically found only in males. When paired with an X chromosome from the mother, it produces a male child.

Yerkes-Dodson law
the principle that performance increases with arousal only up to a point, beyond which performance decreases.

Young-Helmholtz trichromatic (three-color) theory

the theory that the retina contains three different types of color receptors—one most sensitive to red, one to green, one to blue—which, when stimulated in combination, can produce the perception of any color.

zygote
the fertilized egg; it enters a 2-week period of rapid cell division and develops into an embryo.

Subject Index

Note: Page numbers followed by *f* indicate figures; those followed by *t* indicate tables. Page numbers preceded by A, B, or C refer to the appendices.

A

Absolute threshold, 215–216, 215*f*
Abuse. *See* Child abuse and neglect
Academic problem-solving intelligence, 355
Acceptance, in Rogers' person-centered perspective, 530
Acceptance and commitment therapy (ACT), 611
Accidents
    alcohol and, 114
    human factors in, C–13
    in late adulthood, 203, 203*f*
    selective attention and, 91–92
    sleep loss and, 104, 104*f*
Accommodation
    in cognitive development, 176
    visual, 224
Accreditation, B–2

Acculturative stress, 443
Acetylcholine (ACh), 59*t*, 60
Achievement
deliberate practice and, 356
grit and, 356
intelligence and, 354–355, 356*f*
ten-year rule and, 356
Achievement motivation, 412–414, 527
extrinsic, 413–414
goal setting and, 414
intrinsic, 413
Achievement tests, 358. *See also* Intelligence tests
Acid (LSD), 120–121
Acquired immune deficiency syndrome (AIDS), 395
stress and, 448
Acquisition, in conditioning, 264–265, 265*f*, 279*t*
Action potential, 55*f*, 56, 57*f*
Activation-synthesis theory, 109, 110*t*
Active learning, 17–18, 324
Active listening, 603
Acute schizophrenia, 583–584
Adaptability, 259–260
Adaptation
happiness and, 435
natural selection and, 137–141
perceptual, 238

sensory, 218–219, 218*f*
Adaptation-level phenomenon, 435
Addiction(s)
behavior, 113
substance use disorders and, 112, 267. *See also* Psychoactive drugs,
withdrawal in, 113
ADHD (attention-deficit/hyperactivity disorder), 186, 563*f*, 596–597
Adolescence, 190–199
bipolar disorder in, 576
cognitive development in, 193–196, 194*t*
death penalty and, 193
defined, 191
depressive disorders in, 577, 577*f*
egocentrism in, 193
gender differences in social connectedness and power in, 155
health promotion and, 197
memory in, 204–205
peer influence in. *See* Peer relationships
physical development in, 191–193, 192*f*
pregnancy in, 396–397
sex education in, 397
sexual development in, 156–157, 157*f*. *See also* Puberty
sexual risk taking in, 396–397
sleep loss in, 103
smoking and vaping in, 117, 123–124, 124*f*

social development in, 191, 196–199, 196*t*
social disconnection in, 191
social media in, 197, 408–411. *See also* Social media
substance use disorders in, 121, 122, 123–124, 124*f*
Adopted children, 131–132. *See also* Twin and adoption studies
Adrenal glands, 65
Adrenaline, 65
Adulthood, 200–212
cognitive development in, 204–206, 204*f*, 206*f*
commitments in, 207–209
early, 155, 200, 204–205
emerging, 199
late, 200
love in, 207–208
middle, 200, 207, 211
physical development in, 200–204
social development in, 206–211
work in, 209
Adverse experiences, in childhood, 185–187. *See also* Child abuse and neglect; Poverty; Resilience
Aerobic exercise
aging and, 203–204
benefits of, 460–462, 462*f*
depression and, 624, 626
eating disorders and, 592
therapeutic effects of, 624, 626

Afferent (sensory) neurons, 61
Affiliation, 404–411. *See also* Social connectedness
Affiliation motivation, 404–411, 527
Afterimages, 228, 228*f*
Age/aging. *See also specific age groups*
biopsychosocial approach to, 210
brain changes and, 203
depressive disorders and, 577, 577*f*
discrimination and, 489
exercise and, 203–204
intelligence and, 368
language learning and, 343, 344*f*
memory and, 204–205, 204*f*, 206*f*, 308, 309, 323. *See also* Alzheimer's disease
mental, 360
olfaction and, 252
at onset of psychological disorders, 583
sexuality and, 392
sleep and, 109, 109*f*
stress-related, 446
successful, 209–210
Aggression, 497–503. *See also* Violence
alcohol and, 498–499
aversive events and, 499
biochemical influences on, 498–499
biology of, 497–499

biopsychosocial approach to, 502, 502*f*
in children, 500
cocaine and, 119
cultural aspects of, 500
defined, 152, 497
frustration and, 499
gender differences in, 152
gun ownership and, 497, 497*f*, 500
imitation of, 285, 286*f*, 289
microaggressions and, 489
modeling of, 285, 286*f*, 289, 500
neural influences on, 498
psychological and social-cultural factors in, 499–502, 502*f*
punishment and, 275–276
relational, 152
sexual, 141, 160, 395–396
violence-viewing effect and, 289, 500–501
Agonists, 60–61
Agoraphobia, 566
Agreeableness, 536–538, 536*t*, 537*f*
Agree-disagree questionnaires, 527
Aha! moment, 328–329, 328*f*
AIDS (acquired immune deficiency syndrome), 395
stress and, 448
Alcohol, 122*t*
accidents and, 114

aggression and, 498–499
as depressant, 114–116
depression and, 579
disinhibition and, 114
sexual risk taking and, 396–397
use by women, 114, 171
use during pregnancy, 171
Alcohol use disorder, 114
Alcoholics Anonymous (AA), 612
Algorithms, problem solving and, 328, 337*t*
All-or-none response, 56–57
Alpha waves, 97, 97*f*
Alternative hypothesis, 49
Alternative therapies, 618
Altruism, 509–511
Alzheimer's disease, 205–206, 206*f*, 294, 308, 314
reminiscence therapy for, 309
American Academy of Pediatrics, 290
American Academy of Sleep Medicine, 97
American Psychological Association (APA), 275, 399, 621
on bias in intelligence testing, 376
on death penalty for adolescents, 193
divisions in, B–1
ethical guidelines for research, 39
on spanking, 275
on viewing of violence, 290

women in, 6, A–2
Amnesia. *See also* Forgetting; Memory
anterograde, 313–314
infantile, 175, 306
retrograde, 313
source, 320
Amphetamines, 116, 119
Amplitude
of light waves, 223, 223*f*
of sound waves, 241
Amygdala, 73, 73*f*, 75*f*
emotion and, 419–420, 422
fear and, 572, 572*f*
memory and, 306–307, 306*f*
Amytal, 115
Anal stage, in Freud's theory, 521, 521*t*
Analytical intelligence, 355
Androgen, 156
Androgyny, 159
Anger, 428, 428*f*, 432–433
Animals. *See also* Nonhuman primates
cultural transmission by, 338
language in, 349–350
olfaction in, 251
personalities of, 534
in research studies, 39–40, 183–184

same-sex attraction in, 399–400
sleep in, 101, 101*f*, 110
social learning in, 286
taste aversion in, 281–282
thinking by, 337–339
Anorexia nervosa, 554, 563*f*, 583*t*, 592–594
Anosmia, 250
Antagonists, 60
Anterior cingulate cortex, 407
in anxiety, 572, 572*f*
Anterograde amnesia, 313–314
Antianxiety drugs, 625
Antidepressant drugs, 58, 59*f*, 579, 625–626
Antipsychotic drugs, 623–625
Antisemitism, 495
Antisocial behavior, 486, 488–503
aggression, 275–276, 497–503. *See also* Aggression; Violence
modeling of, 285, 286*f*, 289
prejudice and, 488–496
Antisocial personality disorder, 556, 590–592, 590*t*
Anvil (of ear), 241, 242*f*
Anxiety hierarchy, 605
Anxiety/anxiety-related disorders, 563*f*, 565–567
age of onset of, 583*t*
biology of, 571–572
brain areas involved in, 572, 572*f*

child abuse and, 266*f*
cognitive influences in, 571
cognitive-behavioral therapy for, 610–611
conditioning and, 570–571
Covid-19 pandemic and, 568
drug therapy for, 625
free-floating, 566
gender and, 571
generalized anxiety disorder, 266, 556, 565–566, 572
genetic factors in, 571–572
hearing loss and, 240
heritability of, 581*f*
obsessive-compulsive disorder, 568–569, 568*t*, 610–611
panic disorder, 566, 572
posttraumatic stress disorder, 454, 555, 565
psychedelics for, 626–627
race/ethnicity and, 570
social anxiety, 565, 570
social media and, 411
specific phobias, 138, 565, 566–567, 567*f*, 572
stranger, 182
Anxious attachment, 185
Apes. *See* Nonhuman primates
Aphasia, 345
Appearance
attractiveness and, 505–507

prejudice and, 489
Appetite, hunger and, 385–386, 386*f*, 387*f*
Applied research, 14
Approach and avoidance motives, 444–445
Aptitude, creativity and, 335
Aptitude tests, 358. *See also* Intelligence tests
culture-fair, 376
Archetypes, 523
Arcuate nucleus, 386
Arousal, emotions and, 417–419
Arousal theory, 380, 381–382, 383*t*
Artificial intelligence, 277
Asch's conformity studies, 477, 481–482
Asexual orientation, 391, 398. *See also* Sexual orientation
Asian Americans
prejudice against, 495
psychotherapy and, 620
Asperger syndrome, 595–596
Assessment center approach, 543
Assimilation, in cognitive development, 176
Assistive listening technology, C–13
Association areas, 79–81
Associative learning, 260–262
classical conditioning and, 262–268, 279
operant conditioning and, 269–279
Athletics

operant conditioning in, 277
sleep and, 102
sport psychologists and, B–5
Ativan, 625
Attachment, 182–185, 185*f*, 185*t*
anxious, 185
avoidant, 185
contact comfort and, 182, 182*f*
critical period for, 182–183
defined, 182
deprivation of, 185–186
differences in, 183–185, 185*f*, 185*t*
familiarity and, 183
insecure, 183
later relationships and, 185
origins of, 182–183, 182*f*
secure, 183
Attention
selective, 91–92, 92*f*, 93*f*, 249, 495–496, 582
sleep loss and, 104
video games and, 205
Attention-deficit/hyperactivity disorder (ADHD), 186, 563*f*, 596–597
Attitude(s)
actions and, 470–473, 471*f*, 480
cognitive dissonance and, 480
defined, 470

role-playing and, 472
scientific, 3, 4
Attraction, 503–509
liking gap and, 507
modern matchmaking and, 504–505, 505*f*
physical, 505–507
proximity and, 504
reward theory of, 507
similarity and, 507
Attributions
dispositional, 469
factors affecting, 469–470
real-life effects of, 470
situational, 469
Audition, 240. *See also* Hearing
Auditory cortex, 79, 79*f*, 242
Auditory hallucinations, 79
Auditory nerve, 225, 242
Auditory rehearsal, 297
Authoritarian parenting, 188–189
Authoritative parenting, 188–189
Autism spectrum disorder (ASD), 181, 555, 563*f*, 595–596
biology of, 596
defined, 595
gender and, 596
genetic factors in, 596

theory of mind and, 181, 595
twin studies and, 129
vaccination unrelated to, 596
Autobiographical memory, 313
Autoimmune disease, 447
Automatic patronization, 489–490
Automatic processing, implicit memories and, 297
Autonomic nervous system (ANS), 61, 61*f*, 62
emotions and, 421, 422*f*
Availability heuristic, 329, 330–331, 332, 337*t*, 496
Aversion, taste, 281–282
Aversive conditioning, 606–607, 606*f*
Aversive events, aggression and, 499
Avoidant attachment, 185
Avoidant personality disorder, 590, 590*t*
Awareness, evidence of, 90*f*
Axons, 55, 55*f*
Ayahuasca, 120

B

B lymphocytes, 447*f*
Babbling stage, in language development, 342
Back to sleep position, 175
Balance, 253, 253*f*
Bar graphs, 45, 46*f*

Barbiturates, 115–116
Basal ganglia, 72
memory and, 306, 306*f*
Basal metabolic rate, 386
Basic research, 14
Basic trust, 185
Basilar membrane, 241
Beauty, attractiveness and, 505–507
Beck's cognitive therapy, 608–610, 610*t*
Behavior
antisocial, 486, 488–503. *See also* Antisocial behavior
attitudes and, 470–473, 471*f*, 480
changing your own, 271, 278
compulsive, 567–568
cultural influences on, 144–151
dysfunctional, 552–553
group, 483–487, 484*t*
maladaptive, 552–553
operant, 261
predicting, 38
prosocial, 288–289, 486, 503–517. *See also* Prosocial behavior
respondent, 261, 275, 279*t*
shaping of, 270–271, 278
situational assessment of, 543
Behavior addictions, 113
Behavior feedback effect, 430–431

Notes

Chapter 1: Thinking Critically With Psychological Science (Modules 1–3)

[1]Confession: I [DM] wrote the last part of this sentence on April Fool's Day.

[2]Also sometimes called "*R*ecite."

[3]Boston is south of Paris.

[4]The anagram solution: CHAOS.

[5]The independent variable, which the researchers manipulated, was the implied ethnicity of the applicants' names. The dependent variable, which researchers measured, was the rate of positive responses from the landlords.

[6]The example is inspired by ourworldindata.org/covid-deaths-by-vaccination, which also documented that the U.S. Covid-19 death rate, as of October 2, 2021, was 13 times greater among the unvaccinated than the vaccinated.

[7]The actual standard deviation formula is:

$$\sqrt{\frac{Sum\ \ of\ (deviations\ from\ \ mean)^2}{Number\ of\ scores - 1}}$$

Chapter 3: Consciousness and the Two-Track Mind (Modules 8–10)

[1]So, would the reverse damage lead to the opposite symptoms? Indeed, there are a few such patients—who can see and recognize objects but have difficulty pointing toward or grasping them.

[2]This analogy, adapted here with world-based numbers, was suggested by mathematician Sam Saunders, as reported by K. C. Cole (1998).

Chapter 4: Nature, Nurture, and Human Diversity (Modules 11–13)

[1]Actually, this description of the two Jims errs in one respect: Jim Lewis named his son James Alan. Jim Springer named his James Allan.

Chapter 7: Learning (Modules 21–23)

[1]The “buzzer” (English translation) was perhaps the bell people commonly associate with Pavlov (Tully, 2003). Pavlov used various stimuli, but some have questioned whether he used a bell.

Chapter 8: Memory (Modules 24–26)

[1]The words were bicycle, void, cigarette, inherent, fire, and process.

[2]It was this astronaut's prospective memory that failed.

[3]One of my cookie-scarfing sons, on reading this in his father's textbook years later, confessed he had fibbed "a little."

Chapter 9: Thinking and Language (Modules 27–28)

[1]Answer to SPLOYOCHYG anagram: PSYCHOLOGY

[2]The word is *apple*: pineapple, crabapple, applesauce.

[3]The first answer is 5 cents. The bat would then cost $1.05, for a $1.10 total. If the ball cost the *intuitive* answer of 10 cents, the bat would then have to cost $1.10 (for a bat-and-ball total of $1.20, not $1.10). The second answer is Emily. If you answered incorrectly, don't fret—so do many others (Frederick, 2005; Thomson & Oppenheimer, 2016).

Chapter 10: Intelligence (Modules 29–31)

[1]The correct answer is c.

Chapter 11: What Drives Us: Hunger, Sex, Belongingness, and Achievement (Modules 32–35)

[1]Answer: Figure (c).

[2]The researchers later *debriefed* and reassured the participants.

Chapter 12: Emotions, Stress, and Health (Modules 36–40)

[1](a) happiness, (b) surprise, (c) fear, (d) sadness, (e) anger, (f) disgust.

[2]Credit: Nebraska Nurses Association

Chapter 14: Personality (Modules 45–47)

[1]Some of the late Hans Eysenck's views have been deemed racist and some of his other research has been judged untrustworthy, but his personality concepts remain accepted (O'Grady, 2020).

[2]We couldn't resist throwing that in. But don't worry, you won't be tested on *floccinaucinihilipilification,* which is the act of estimating something as worthless (and was the longest nontechnical word in the first edition of the *Oxford English Dictionary*).

Chapter 15: Psychological Disorders (Modules 48–53)

[1]Also called the *diathesis-stress model*. ("Diathesis"—meaning "predisposed vulnerability"—derives from a Greek word for "predisposition".)

[2]Many examples in the psychological disorders modules were drawn from case studies in a previous DSM edition.

Chapter 16: Therapy (Modules 54–56)

[1]Rogers made this statement at a time when the generic pronoun *he* was meant to describe people of all genders.

Appendix B: Career Fields in Psychology

[1]Although this text covers the world of psychology for students in many countries, this appendix draws primarily from available U.S. data. These descriptions of career fields in psychology do, however, apply to many other countries as well.

Extended description for Learning Curve Adaptive Quizzing

Macmillan Learning

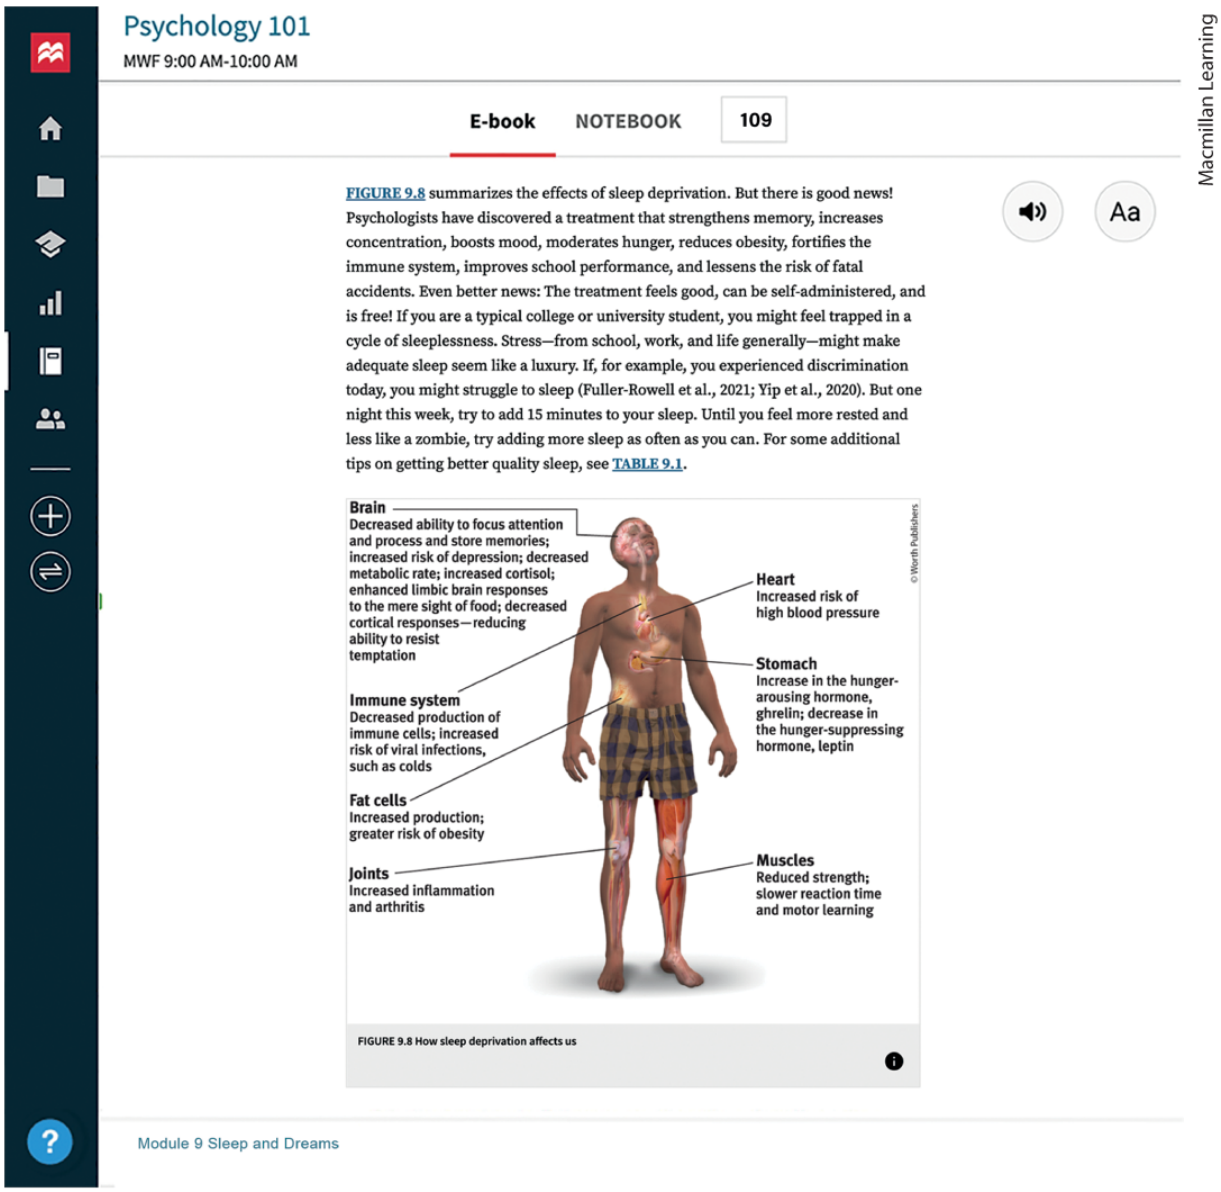
The illustration present on the right depicts the back view of a woman with the brain and spinal cord highlighted within.

The parts aroused by the SYMPATHETIC NERVOUS SYSTEM are labeled as follows: Pupils: Dilates; Heart: Accelerates heartbeat; Stomach, pancreas, and duodenum: Inhibits digestion; Liver: Stimulates glucose release; Adrenal glands: Stimulates secretion of epinephrine and norepinephrine; Bladder.

The PARASYMPATHETIC NERVOUS SYSTEM text is partially covered by a sound icon and the uppercase letter A and small letter A, enclosed in circles. The parts calmed by the parasympathetic nervous system are labeled as follows: Pupils: Contracts; Heart: Slows heartbeat; Stomach, pancreas, and duodenum: Stimulates digestion; Gallbladder: Stimulates bile release; Bladder: Contracts.

On the left, a question reads, Which situation is MOST likely to involve the action of the parasympathetic nervous system? followed by four options represented by radio button choices:

- Brooke's finger accidentally grazes the hot iron: she immediately jerks her hand away.
- After a satisfying evening meal, Callum relaxes in front of the television.
- Walking toward her car in a deserted parking garage one night, Danica is surprised by a strange man who seems to appear from nowhere.
- None of these situations reflects the action of the parasympathetic nervous system.



Among the above options, After a satisfying evening meal, Callum relaxes in front of the television option is marked correct.

Below the options, there are two horizontal bars, one above the other, with the labels Next Question and Take a Break, respectively.

At the top of the screenshot, there are two horizontal bars, with the first bar containing the home icon, the arrow icon enclosed in a circle, and the text LearningCurve 4 b. Infancy and Childhood in the left corner and the question mark enclosed in a circle, Calendar symbol, and text Due: Wed, Mar 31 in the right corner. The second bar contains the text Previewing as a Student in the left corner and End Preview in the right corner. Below the bar, there is the Back to Study button and the Logo: Achieve. Macmillan Learning is written in the top right corner covering the bars.

Return to Learning Curve Adaptive Quizzing

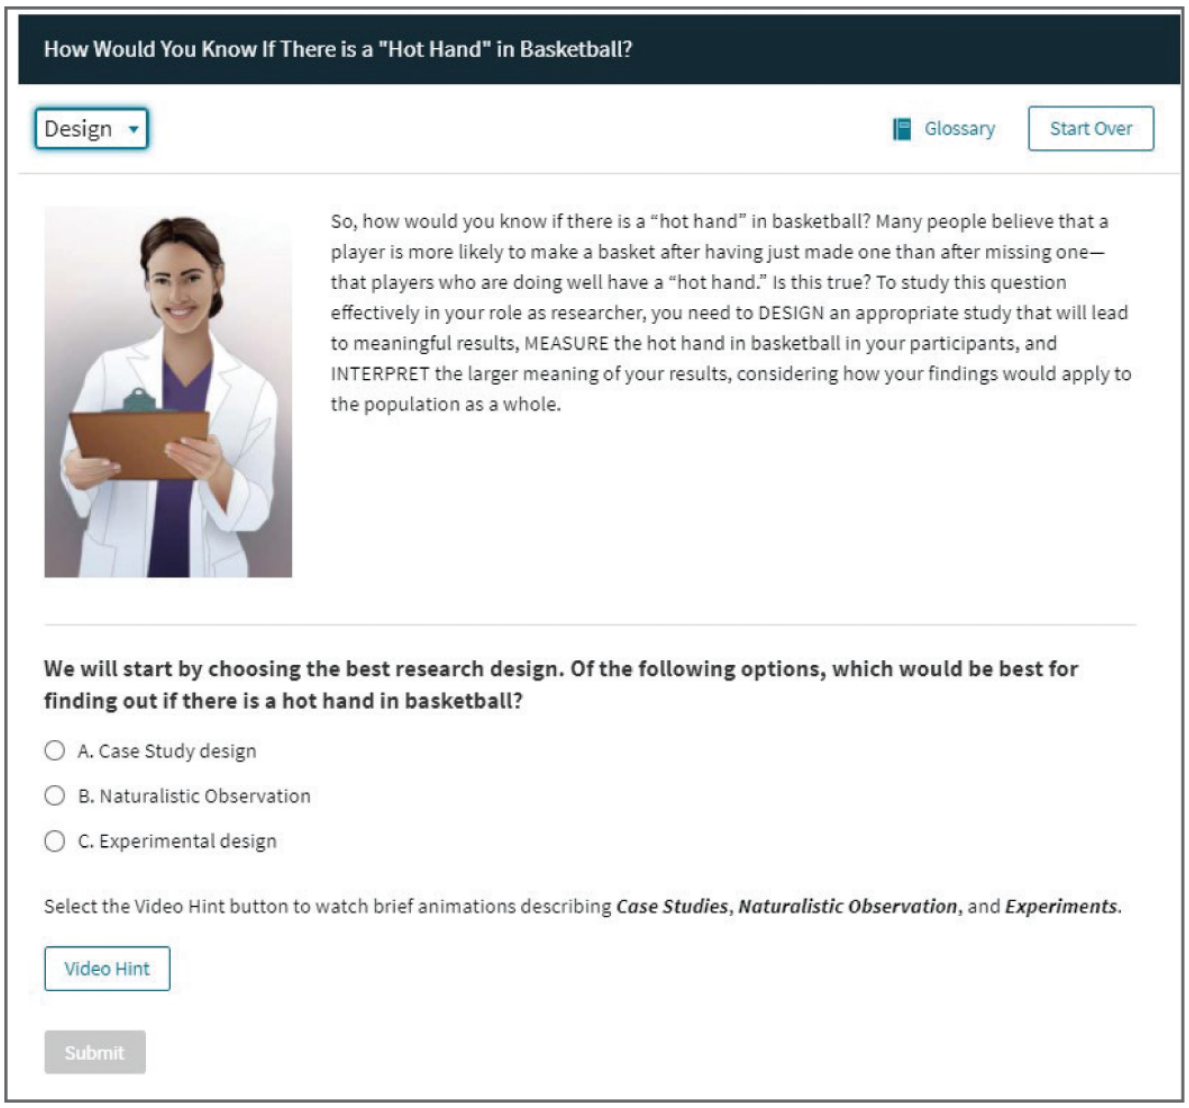
Extended description for E-book page

Macmillan Learning

The descriptions pointing to the different parts read as follows:

- **Brain:** decreased ability to focus attention and process and store memories; increased risk of depression; decreased metabolic rate; increased cortisol; enhanced limbic brain responses to the mere sight of food; decreased cortical responses dash reducing the ability to resist temptation
- **Immune system:** decreased production of immune cells; increased risk of viral infections, such as colds
- **Fat cells:** increased production; greater risk of obesity
- **Joints:** increased inflammation and arthritis; Heart: increased risk of high blood pressure
- **Stomach:** increase in the hunger arousing hormone, ghrelin; decrease in the hunger-suppressing hormone, leptin
- **Muscles:** reduced strength; slower reaction time and motor learning.

Below the illustration is written: FIGURE 9.8 How sleep deprivation affects us on the left and a small letter i enclosed in a circle on the right. At the bottom of the screenshot, Module 9 Sleep and Dreams is written in the extreme left corner.



Above the illustration is written: FIGURE 9.8 summarizes the effects of sleep deprivation. But there is good news. Psychologists have discovered a treatment that strengthens memory, increases concentration, boosts mood, moderates hunger, reduces obesity, fortifies the immune system, improves school performance, and lessens the risk of fatal accidents. Even better news: The treatment feels good, can be self-administered, and is free. If you are a typical

college or university student, you might feel trapped in a cycle of sleeplessness. Stress from school, work, and life generally might make adequate sleep seem like a luxury. If, for example, you experienced discrimination today, you might struggle to sleep (Fuller-Rowell e t a l., 2021; Yip e t a l., 2020). But one night this week, try to add 15 minutes to your sleep. Until you feel more rested and less like a zombie, try adding more sleep as often as you can. For some additional tips on getting better quality sleep, see Table 9.1.

The heading of the screenshot reads Psychology 101 and M W F 9:00 A.M. - 10:00 A.M. parallel to each other. Below the heading, E-book, NOTEBOOK, and 109 enclosed in a rectangular box are written. Below it, a sound icon and an upper letter A small letter a, enclosed in circles, are present. On the extreme left, a vertical bar is present with the following icons: two wavy lines enclosed in a rectangle, a home icon, a folder icon, an icon looking like a square box tilted in the left direction, an icon with three lines increasing in size from left to right, an icon looking like a book, two people icon, a small horizontal line, a plus sign enclosed in a circle, two half arrows parallel in opposite direction and enclosed in a circle, and a question mark enclosed in a circle.

Return to E-book page

Extended description for Test question

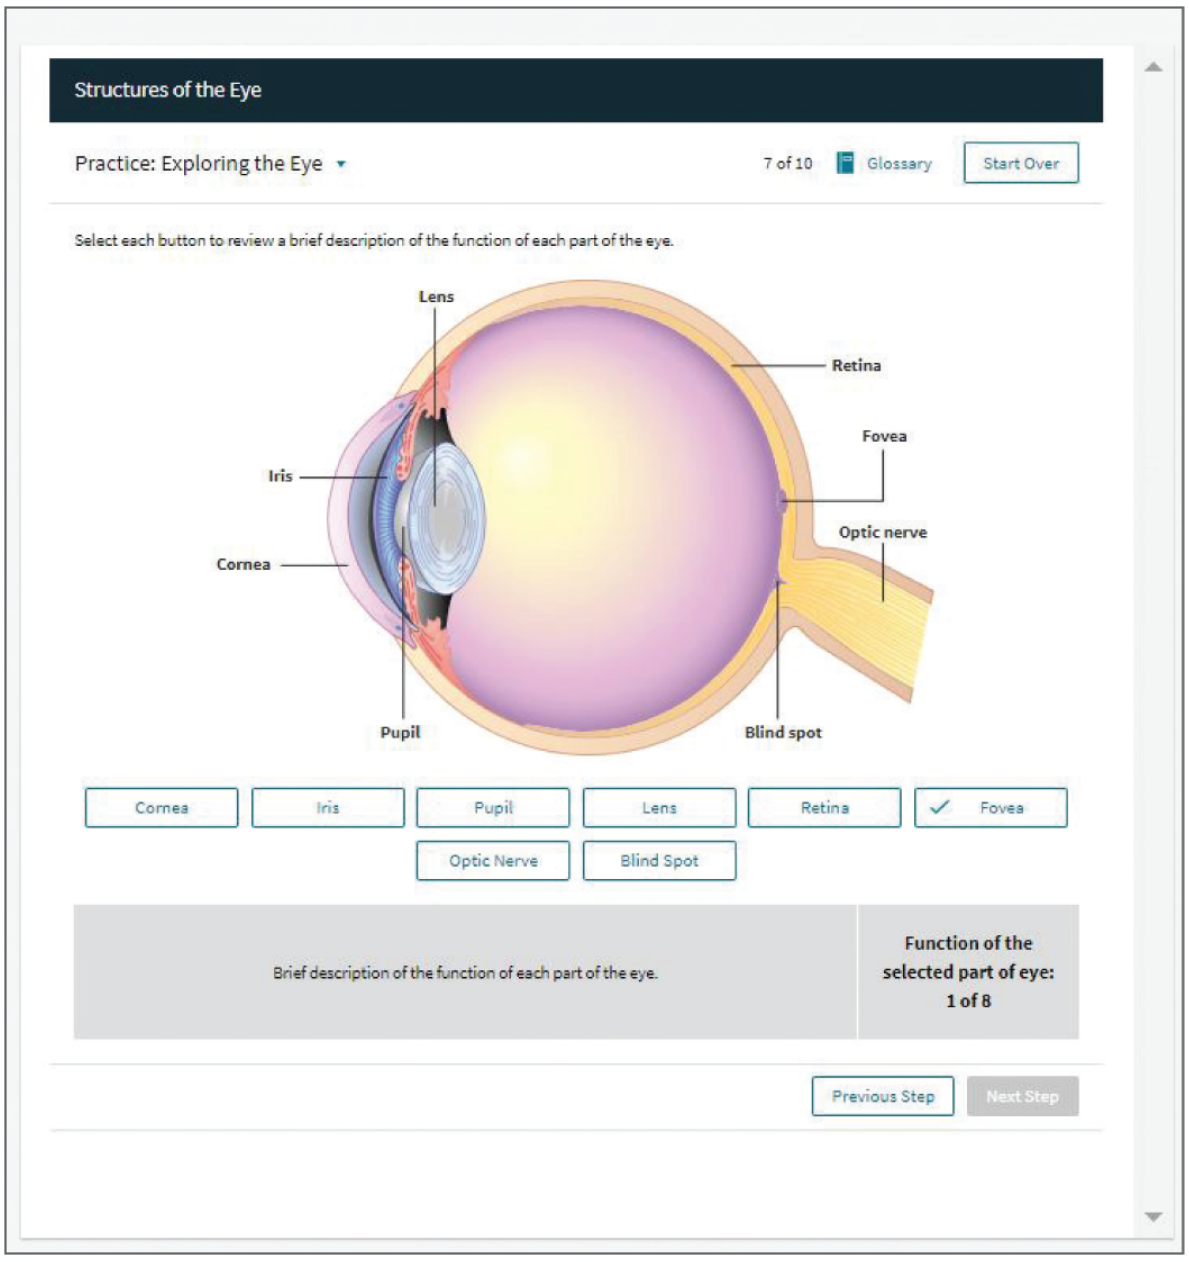
Macmillan Learning

An illustration at the top left shows a woman in a lab coat holding a clipboard. To the right is a paragraph reading, So, how would you know if there is a “hot hand” in basketball? Many people believe that a player is more likely to make a basket after having just made one

than after missing one dash that players who are doing well have a "hot hand." Is this true? To study this question effectively in your role as a researcher, you need to DESIGN an appropriate study that will lead to meaningful results, MEASURE the hot hand in basketball in your participants, and INTERPRET the larger meaning of your results, considering how your findings would apply to the population as a whole.

A question follows the reading, **We will start by choosing the best research design. Of the following options which would be best for finding out if there is a hot hand in basketball?** Three radio button choices read:

A. Case Study design



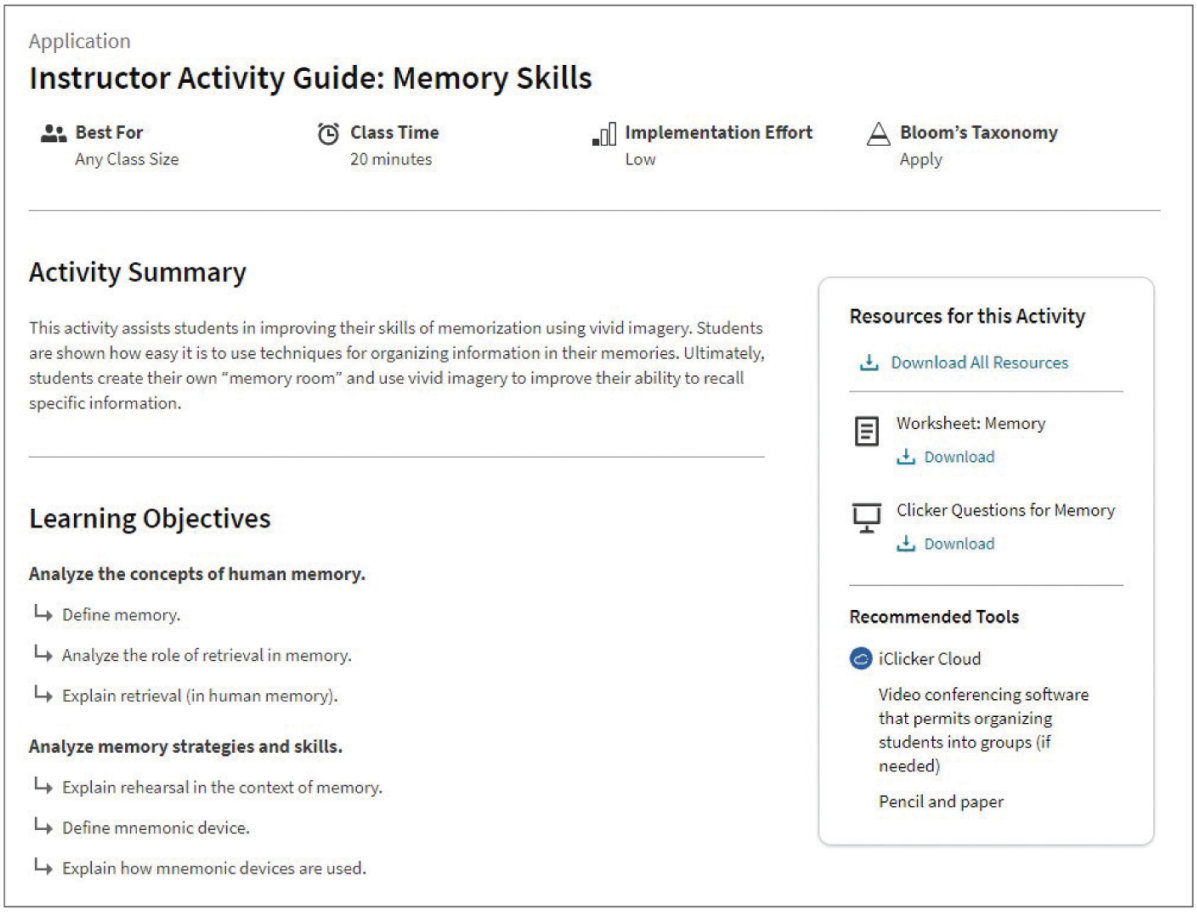
B. Naturalistic observation

C. Experimental design.

Text reads, Select the Video Hint button to watch brief animations describing Case Studies, Naturalistic Observation, and Experiments. A button labeled, Video Hint is at the bottom followed by a Submit button.

Return to Test question

Extended description for Exploring the eye



Macmillan Learning

The heading reads Structures of the Eye. The text below the heading reads, **Practice: Exploring the Eye**. The text on the right reads 7 of

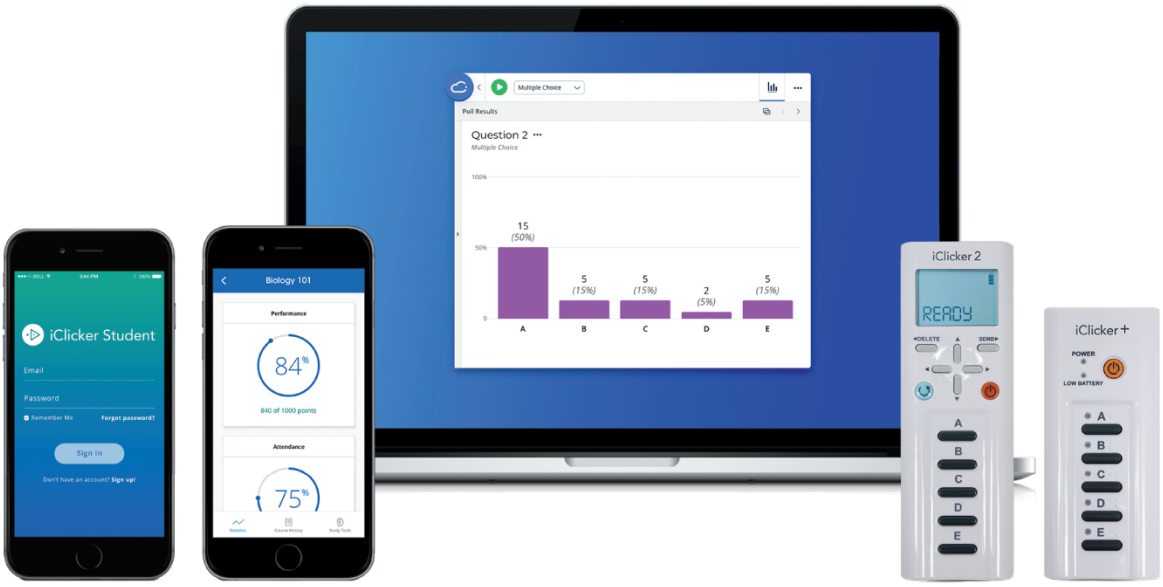
10 and shows a glossary icon and an option to start over. The text above the illustration reads, Select each button to review a brief description of the function of each part of the eye. There are rectangular buttons below the illustration naming the parts of the eye. The buttons read: Cornea, Iris, Pupil, Lens, Retina, Fovea, Optic Nerve, Blind Spot. The bottom left of the screenshot reads, Brief description of the function of each part of the eye. The bottom right reads, Function of the selected part of the eye: 1 of 8. Below are the options to go to the Previous Step or Next Step.

Return to Exploring the eye

Extended description for Instructor Activity Guide

Macmillan Learning

The remainder of the screen is divided into two sections. Text dominating the left side of the screen reads, **Activity Summary** followed by a paragraph which reads, This activity assists students in improving their skills of memorization using vivid imagery. Students are shown how easy it is to use techniques for organizing information in their memories. Ultimately, students create their



own “memory room” and use vivid imagery to improve their ability to recall specific information.

Following the paragraph are **Learning Objectives** with two parts: **Analyze the concepts of human memory** followed by three arrows pointing to text reading, Define memory; Analyze the role of retrieval in memory; and Explain retrieval (in human memory). **Analyze memory strategies and skills** followed by three arrows pointing to text reading, Explain rehearsal in the context of memory; Define mnemonic device; and Explain how mnemonic devices are used.

A sidebar at the right shows **Resources for this Activity** as Worksheet: Memory and Clicker Questions for Memory. Each has the option to download. At the bottom of the sidebar are Recommended Tools, and the text reads i Clicker Cloud. Video conferencing software that permits organizing students into groups (if needed). Pencil and paper.

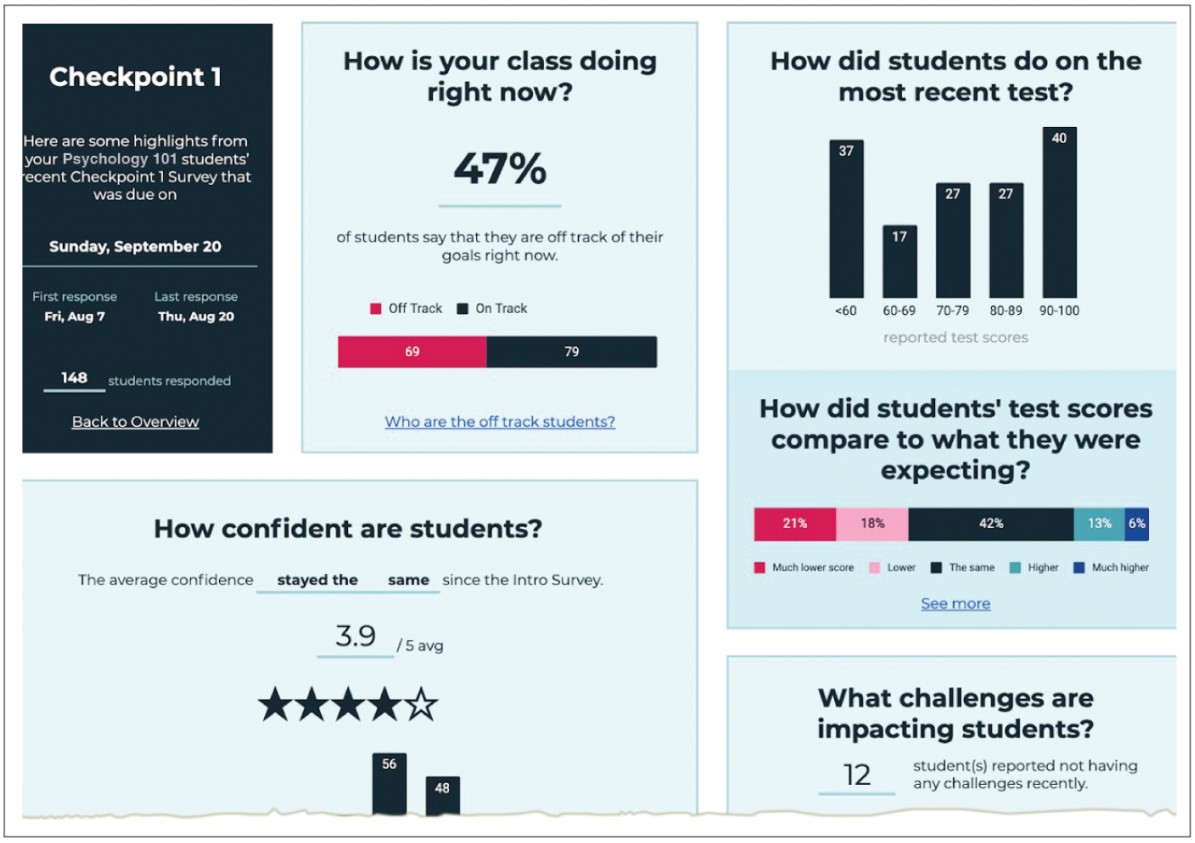
Extended description for Electronics



Macmillan Learning

The left cell phone shows a screen reading BELL, Wifi icon, 3:44 PM, and 100 percent battery at the top, followed by i Clicker Student and a sign-in button with Email, password, remember me, and forgot password? options. The text at the bottom reads, Don't have an account? Sign up. The right cell phone reads, Biology 101 at the top followed by two circles. The top circle shows 84 percent performance, representing 840 of 1000 points, and the bottom one shows 75 percent attendance. The bottom of the screen reads Statistics, Create History, and Study tools. The monitor shows a heading that reads, Multiple Choice. Below it, the text reads, Poll results followed by Question 2, multiple choice, and a bar graph. The vertical axis of the graph is as follows: 0, 50 percent, and 100

percent. The horizontal axis is as follows: A, B, C, D, and E. The data in the bar graph is as follows: A, 15 (50 percent); B, 5 (15 percent); C, 5 (15 percent); D, 2 (5 percent), and E, 5 (15 percent). The two remotes are labeled i Clicker 2 and i Clicker Plus. The i Clicker 2 has a screen reading, Ready with arrow buttons at the top, and 2 buttons among them are labeled delete and send. The five buttons below are marked A, B, C, D, and E. The i Clicker Plus contains power and low battery light and also five buttons below marked A, B, C, D, and E.

Return to Electronics

Extended description for Learning Objectives, Reports, and Insights

Macmillan Learning

The panel at the top left is titled **Checkpoint 1.** The text below reads. Here are some highlights from your Psychology 101 students' recent Checkpoint 1 Survey that was due on Sunday, September 20. First response Fri, August 7; Last response Thursday, August 20. 148 students responded. Back to Overview.

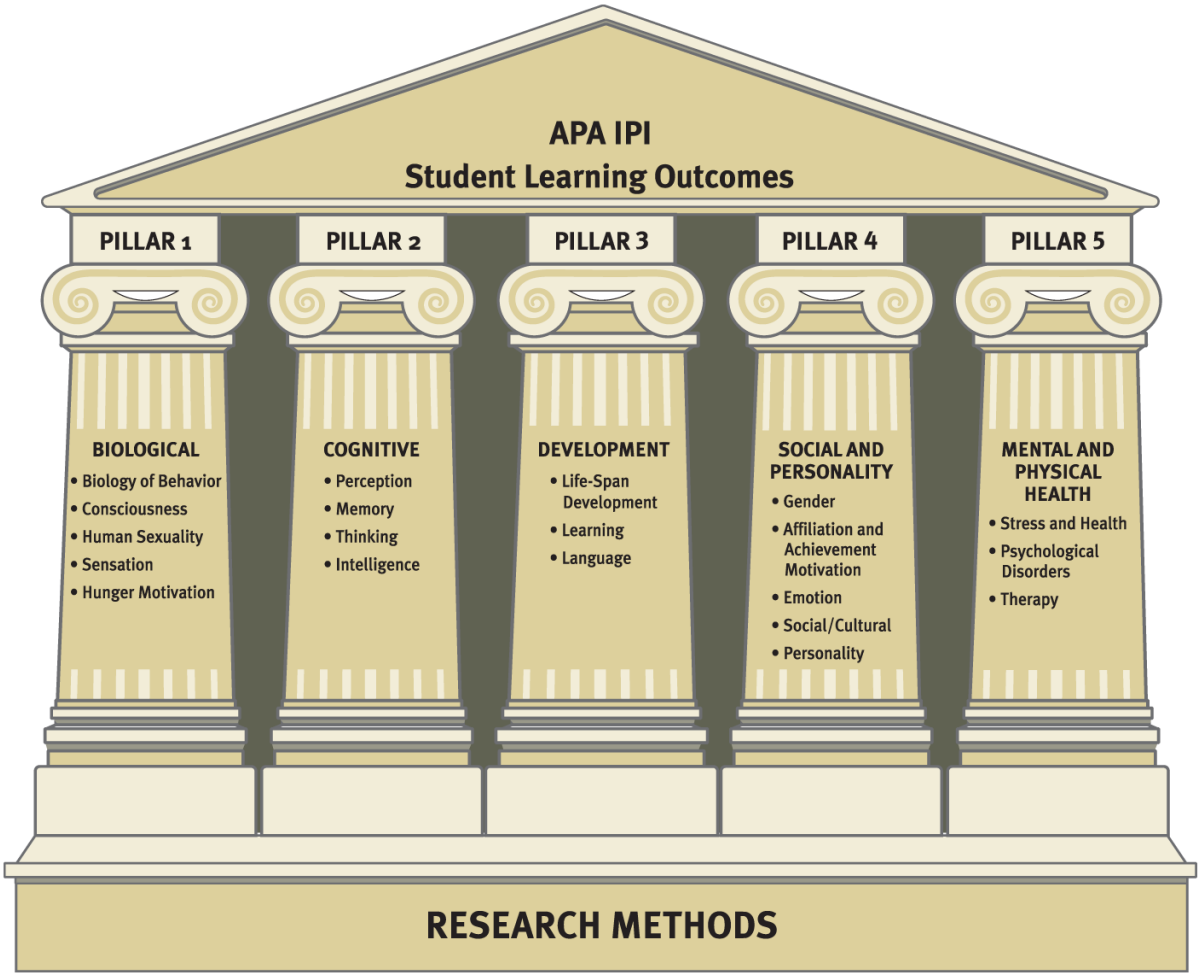
The next panel shows a title that reads, **How is your class doing right now? 47 percent** of students say that they are off track of their goals right now. A two-colored bar shows data as follows. Off Track, 69; On Track, 79. The text below reads, Who are the off track students?

Another panel below reads as follows. **How confident are students?** The average confidence stayed the same since the Intro Survey. **3.9** out of 5 avg. This text is followed by five stars for rating. Out of five stars, four stars are shaded. Below the stars are three vertical bars. The left bar is smaller in size, followed by the middle larger bar labeled 56, and the right bar labeled 48.

A panel on the right shows the text, **How did students do on the most recent test?** This is followed by a bar graph. The horizontal axis of the graph shows reported test scores. The data are as follows.

- Less than 60, 37
- 60 to 69, 17
- 70 to 79, 27
- 80 to 89, 27
- 90 to 100, 40.

Another panel below reads, How did students' test scores compare to what they were expecting? A horizontal bar shows the data, as follows.



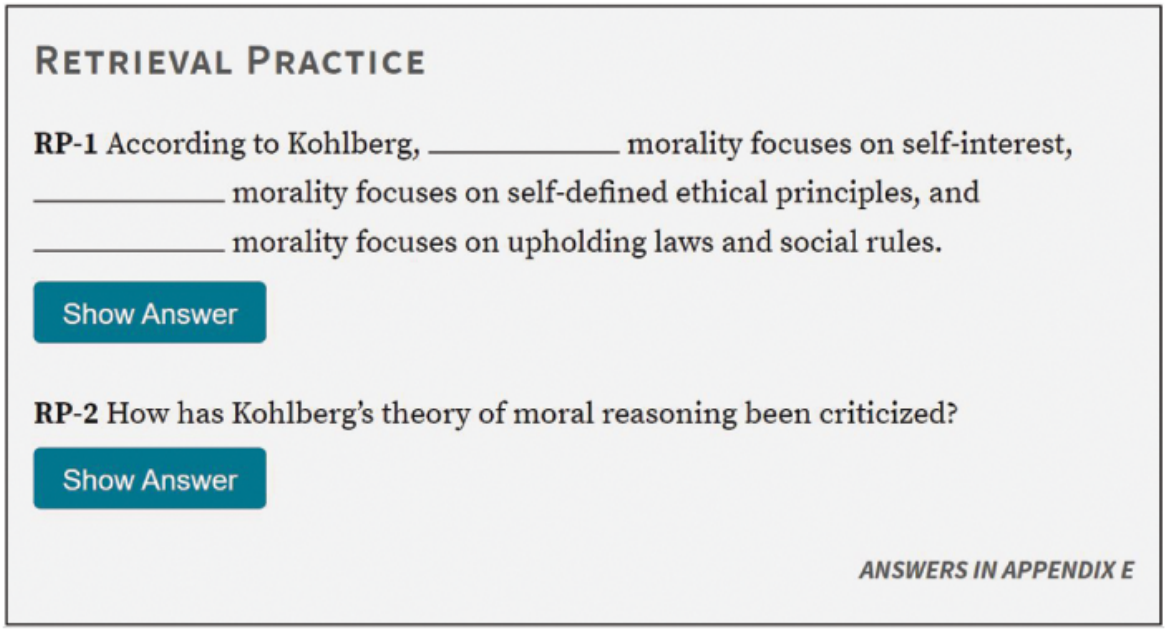
- A much lower score, 21 percent

- Lower, 18 percent
- The same, 42 percent
- Higher, 13 percent
- Much higher, 6 percent. See more.

The last panel on the bottom right shows the text as follows. **What challenges are impacting students?** 12 student (s) reported not having any challenges recently.

Return to Learning Objectives, Reports, and Insights

Extended description for FIGURE 1 Student pillars for introductory psychology



Macmillan Learning

The pillars have titles and bulleted text. **Pillar 1** reads, **Biological.** The bullets read, Biology of Behavior, Consciousness, Human Sexuality, Sensation, Hunger Motivation. **Pillar 2** reads, **Cognitive.**

The bullets read Perception, Memory, Thinking, Intelligence. **Pillar 3** is **Development,** and bullets read, Life-span Development, Learning, Language. **Pillar 4** is **Social and Personality**, and bullets read, Gender, Affiliation and Achievement Motivation, Emotion, Social slash Cultural, Personality. **Pillar 5** is **Mental and Physical Health.** The bullets read Stress and Health, Psychological Disorders, and Therapy.

Return to FIGURE 1 Student pillars for introductory psychology

Extended description for FIGURE 3 Sample Retrieval Practice feature

The text reads, **R P-1** According to Kohlberg, blank space, morality focuses on self-interest, blank space, morality focuses on self-defined ethical principles, and, blank space, morality focuses on upholding laws and social rules. A button reads, Show Answer.

R P-2 How has Kohlberg's theory of moral reasoning been criticized? A button reads, Show Answer.

Text in the bottom right corner reads, ***Answers in Appendix E.***

Return to FIGURE 3 Sample Retrieval Practice feature

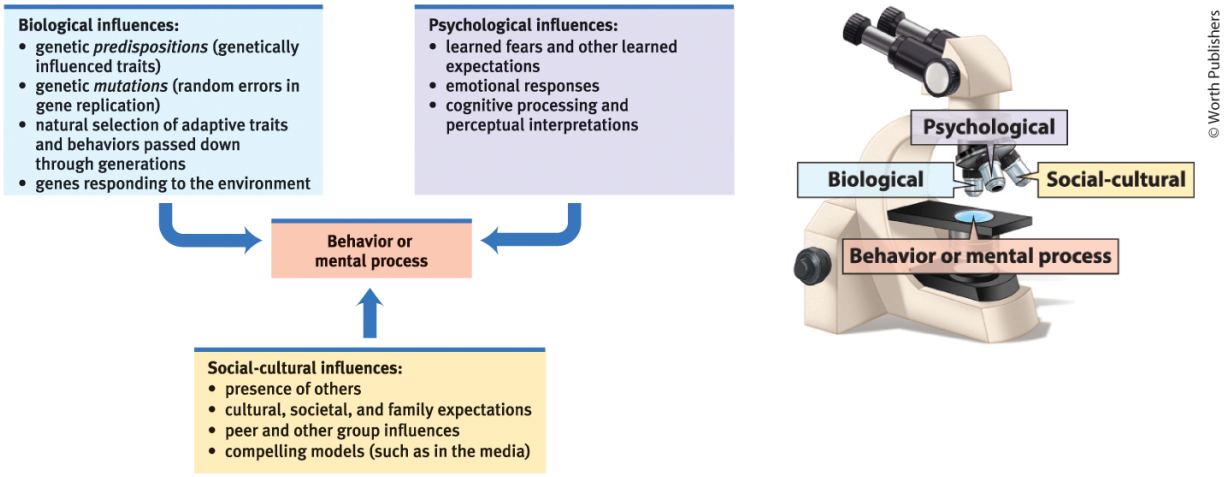
Extended description for The scientific attitude

© Worth Publishers

Text at the top reads, **Thinking Critically About: The Scientific Attitude**. Three basic attitudes helped make modern science possible.

The three sections are as follows:

1. Curiosity: Does it work? When put to the test, can its predictions be confirmed? An illustration shows a woman wearing a lab coat with a clipboard in her hand. Two thought bubbles are depicted from her head. The top bubble shows an illustration of a woman touching her head with one hand and a man's head with another hand. Text reads, Can some people read minds? The corresponding text under the image of the scientist reads, No one has yet been able to demonstrate extrasensory mind-reading. The lower bubble shows an illustration of a stressed-out boy with his hands on his head. Text reads, Are stress levels related to health and well-being? The corresponding text under the image of the scientist reads, Many studies have found that higher stress relates to poorer health.



2. Skepticism: What do you mean? How do you know? Sifting reality from fantasy requires a healthy skepticism dash an attitude that is not cynical (doubting everything), but also not gullible (believing everything). An illustration shows a man standing with his shoulders slumped forward. Text reads, Do our facial expressions and body postures affect how we actually feel? The corresponding text at the bottom of the section reads, Our facial

expressions and body postures can affect how we feel. Another illustration shows a woman pushing a child on a swing. Text reads, Do parental behaviors determine children's sexual orientation? The corresponding text at the bottom of the section reads, Module 34 explains that there is not a relationship between parental behaviors and children's sexual orientation.

3. Humility: That was unexpected! Let's explore further. Researchers must be willing to be surprised and follow new ideas. People and other animals don't always behave as our ideas and beliefs would predict. An illustration shows a woman in a lab coat looking at her clipboard. Another illustration shows a rat in a conditioning chamber, pressing a lever, with an object emerging out from a window above the lever. Text reads, The rat is always right.

Return to The scientific attitude

Extended description for FIGURE 1.1 Biopsychosocial approach

© Worth Publishers

A text box in the center reads, Behavior or mental process. A text box at the top left reads, **Biological influences**: Genetic *predispositions* (genetically influenced traits); genetic *mutations* (random errors in gene replication); natural selection of adaptive traits and behaviors passed down through generations; and genes responding to the environment. A text box at the top right reads, **Psychological influences**: Learned fears and other learned expectations; emotional responses; and cognitive processing and perceptual interpretation. A text box at the bottom reads, **Social-cultural influences**: Presence of others; cultural, societal, and family expectations; peer and other group influences; and

compelling models (such as in the media). All three boxes have arrows pointing to the central box.

An image beside the chart shows a microscope, with its three lenses labeled Biological, Psychological, and Social-cultural, and the platform labeled Behavior or mental process.

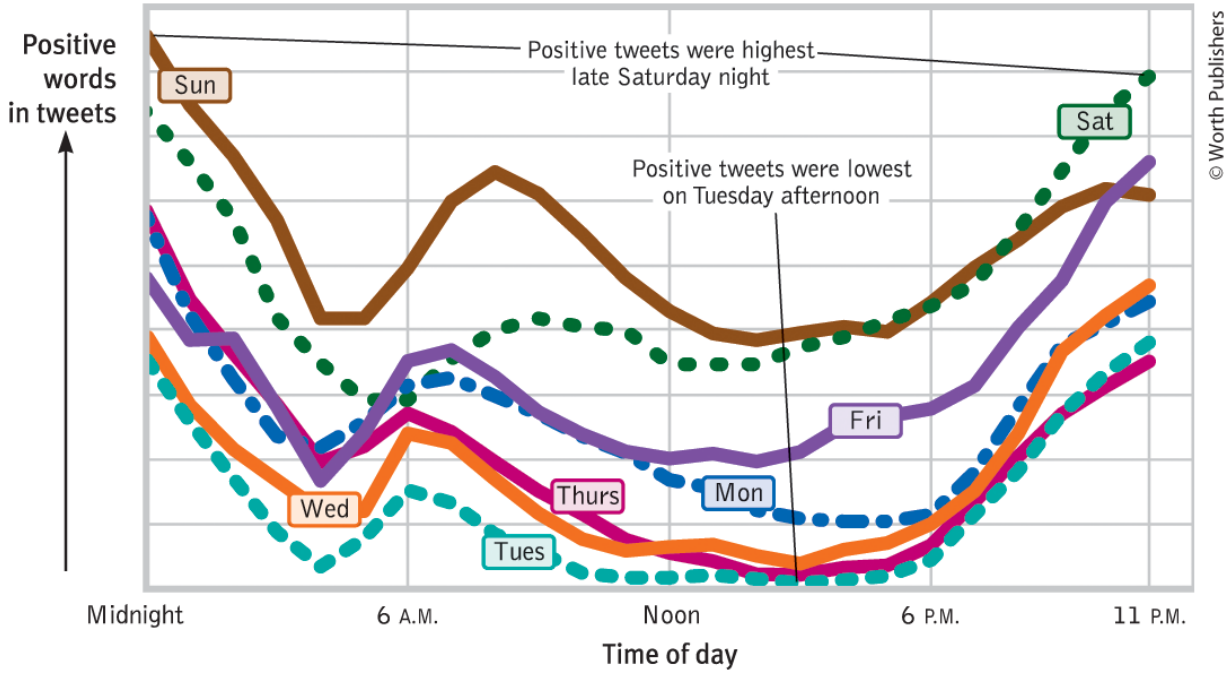
Extended description for FIGURE 2.2 The scientific method



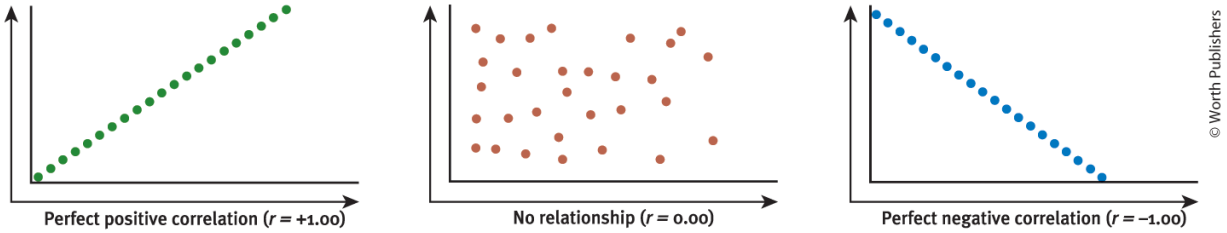
© Worth Publishers

The scientific method is depicted by three boxes connected by clockwise arrows. The top box reads, Theories. *Example*: Sleep boosts memory. An arrow labeled, lead to, points to a box on the right that reads, Hypotheses. *Example*: When sleep deprived, people remember less from the day before. An arrow labeled, lead to, points to a box on the left, that reads, Research and observations. *Example*: Give study material to people before (a) an ample night's

sleep or (b) a shortened night's sleep, then test memory. An arrow labeled, confirm, reject, or revise, points back to the top box.

Return to FIGURE 2.2 The scientific method

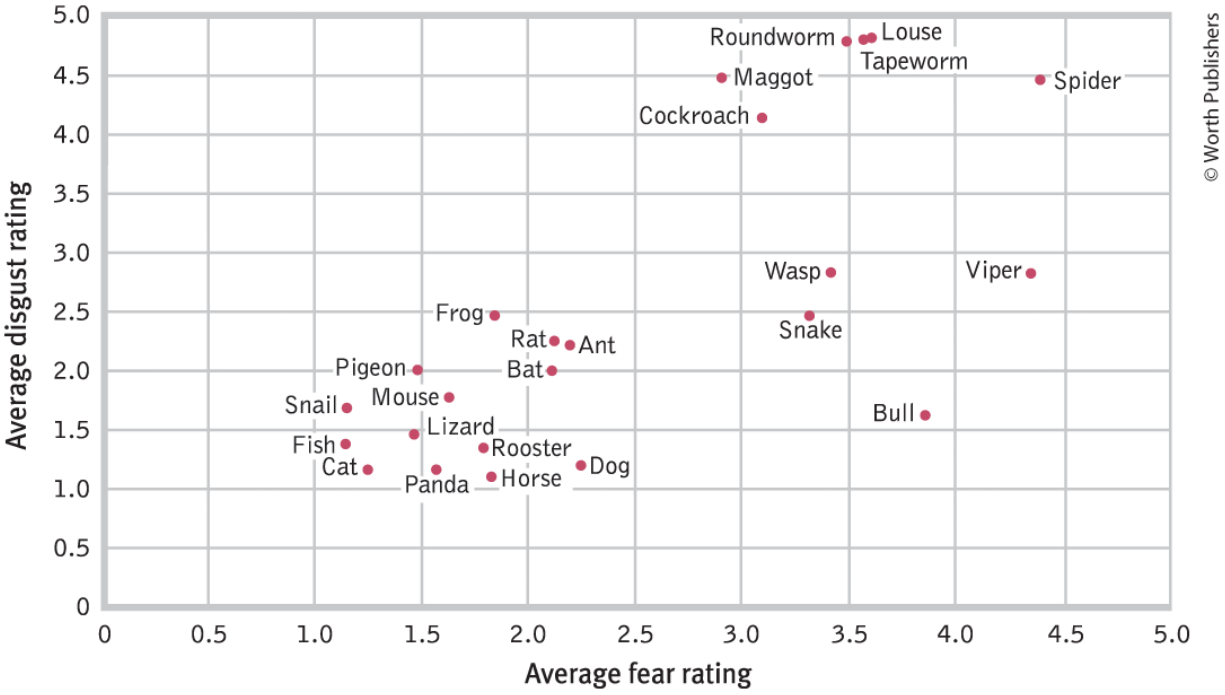
Extended description for FIGURE 2.3 Twitter message moods, by time and by day



The horizontal axis represents time of day and ranges from midnight to 11 P.M. The vertical axis represents positive words in tweets and increases from bottom to top. Six curves are plotted on the graph with each corresponding to one day of the week. In general, Sunday and Saturday have the most positive words, with text stating that positive tweets were highest late Saturday night. Tuesday and Wednesday have the fewest positive words, with text stating that positive tweets were lowest on Tuesday afternoon. With

regard to time of day, in general, each day shows the most positive tweets around 11 P.M. and midnight, and the fewest positive tweets between noon and 6 P.M.

Return to FIGURE 2.3 Twitter message moods, by time and by day

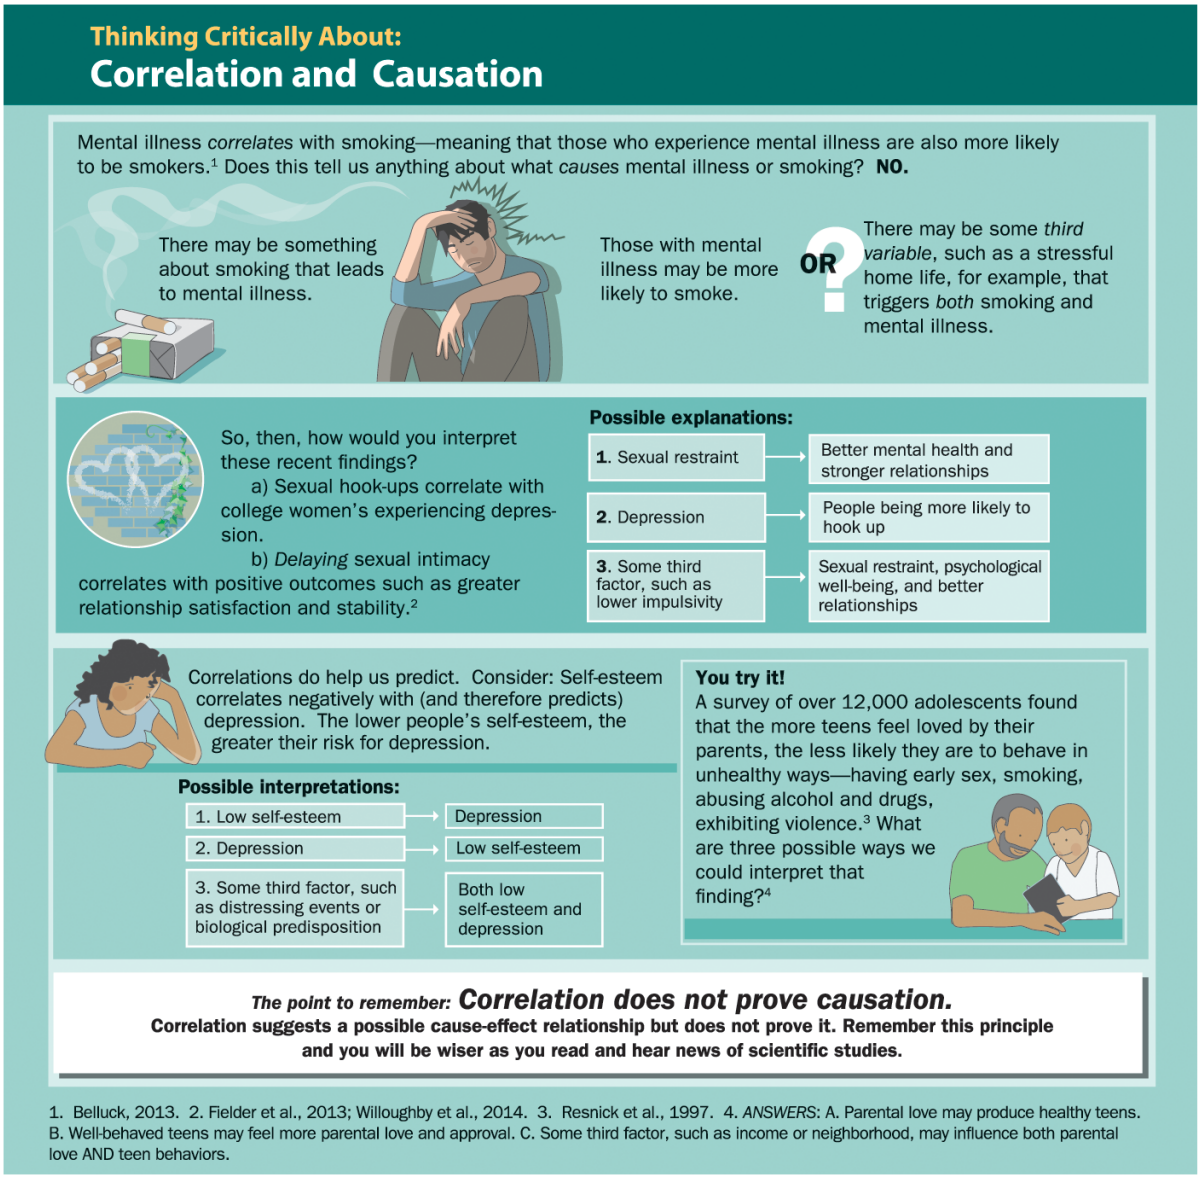


Extended description for FIGURE 2.4 Scatterplots, showing patterns of correlation

(a) The horizontal axis is labeled Perfect positive correlation (*r* equals positive 1.00) and shows a linear positive slope from the lower left to the upper right marked with dots. (b) The horizontal axis is labeled No relationship (*r* equals 0.00) and shows dots scattered throughout. (c) The horizontal axis is labeled Perfect negative correlation (*r* equals negative 1.00) and shows a linear negative slope marked with dots from the upper left to the lower right.

Return to FIGURE 2.4 Scatterplots, showing patterns of correlation

Extended description for FIGURE 2.5 Scatter plot for fear and disgust felt toward 24 animals



The horizontal axis represents average fear rating and ranges from 0 to 5.0, in increments of 0.5. The vertical axis represents average disgust rating and ranges from 0 to 5.0, in increments of 0.5. The plots on the graphs are labeled as follows: Snail (1.1, 1.7); Fish (1.1, 1.4); Cat (1.25, 1.2); Pigeon (1.5, 2.0); Lizard (1.5, 1.5); Panda (1.6, 1.2); Mouse (1.6, 1.7); Rooster (1.7, 1.4); Horse (1.8, 1.1); Frog (1.7, 2.5); Bat (2.1, 2.0); Rat (2.1, 2.3); Ant (2.2, 2.25); Dog (2.25, 1.25); Maggot (2.9, 4.5); Cockroach (3.1, 4.1); Snake (3.3, 2.5); Wasp (3.4,

2.9); Roundworm (3.5, 4.75); Tapeworm (3.6, 4.75); Louse (3.62, 4.74); Bull (3.8, 1.6); Viper (4.3, 2.85); and Spider (4.4, 4.5). All data are approximate.

Return to FIGURE 2.5 Scatter plot for fear and disgust felt toward 24 animals

Extended description for Correlation and causation

© Worth Publishers

Text at the top reads, **Thinking critically about: Correlation and Causation**. The infographic shows three sections as follows:

Section 1: Mental illness *correlates* with smoking dash meaning that those who experience mental illness are also more likely to be smokers (Belluck, 2013). Does this tell us anything about what causes mental illness or smoking? **NO**. An illustration shows a pack of cigarettes. Text above reads, There may be something about smoking that leads to mental illness. Another illustration shows a distressed man sitting on the floor with hands on his head. Corresponding text reads, Those with mental illness may be more likely to smoke. The word **OR** is presented over a question mark. Corresponding text reads, There may be some *third variable*, such as a stressful home life, for example, that triggers *both* smoking and mental illness.

Section 2: An illustration shows two overlapping heart shapes inside a circle. Corresponding text reads, So, then, how would you interpret these recent findings? a) Sexual hook-ups correlate with college women's experiencing depression. b) *Delaying* sexual intimacy correlates with positive outcomes such as greater relationship satisfaction and stability (Fielder et al., 2013; Willoughby et al., 2014). **Possible explanations:** 1. Sexual restraint leading to better mental health and stronger relationships. 2. Depression leading to people being more likely to hook up. 3. Some third factor, such as lower impulsivity leading to sexual restraint, psychological well-being, and better relationships.

Section 3: An illustration shows a young woman seated at a table looking sad and resting her head on her hand. Corresponding text reads, Correlations do help us predict. Consider: Self-esteem correlates negatively with (and therefore predicts) depression. The lower people's self-esteem, the greater their risk for depression. **Possible interpretations**: 1. Low self-esteem leads to depression. 2. Depression leads to low self-esteem. 3. Some third factor, such as distressing events or biological predisposition, leads both low self-esteem and depression. An illustration shows a man and a boy looking at a book together. Text reads, **You try it!** A survey of over 12,000 adolescents found that the more teens feel loved by their parents, the less likely they are to behave in unhealthy ways dash having early sex, smoking, abusing alcohol and drugs, exhibiting violence (Resnick et al., 19 97). What are three possible ways we could interpret that finding? Answers: A. Parental love may produce healthy teens. B. Well-behaved teens may feel more parental love and approval. C. Some third factor, such as income or neighborhood, may influence both parental love AND teen behaviors.

A textbox at the bottom of the infographic reads, The point to remember: **Correlation does not prove causation**. Correlation suggests a possible cause-effect relationship but does not prove it. Remember this principle and you will be wiser as you read and hear news of scientific studies.

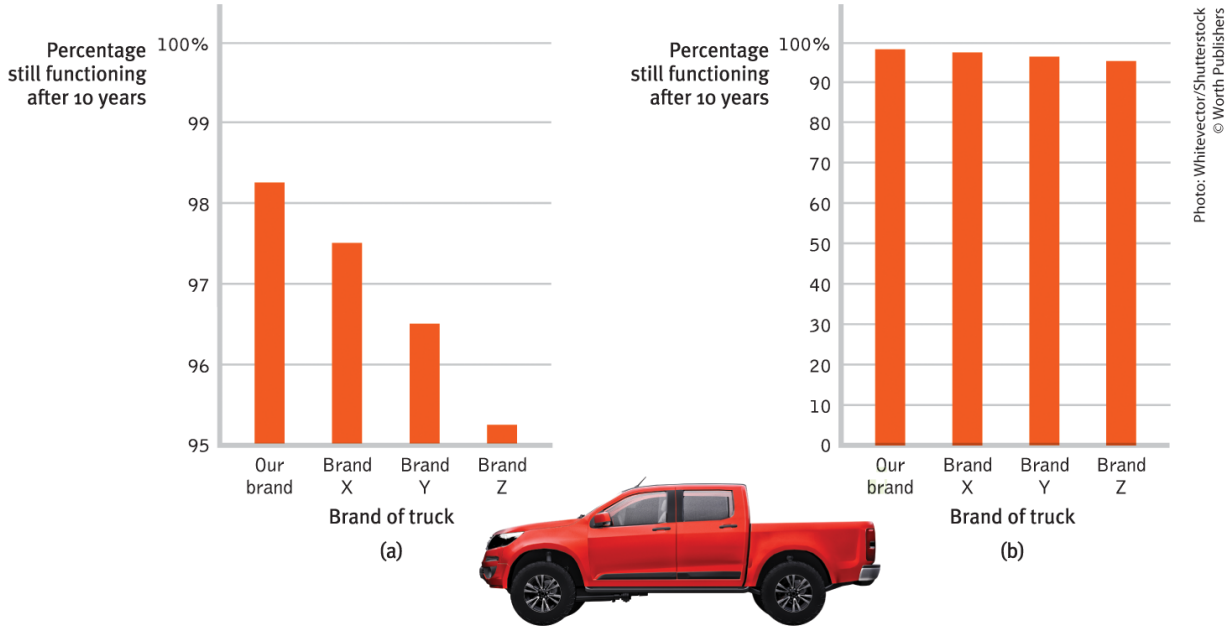
Extended description for FIGURE 3.1 Statistical literacy for vaccines

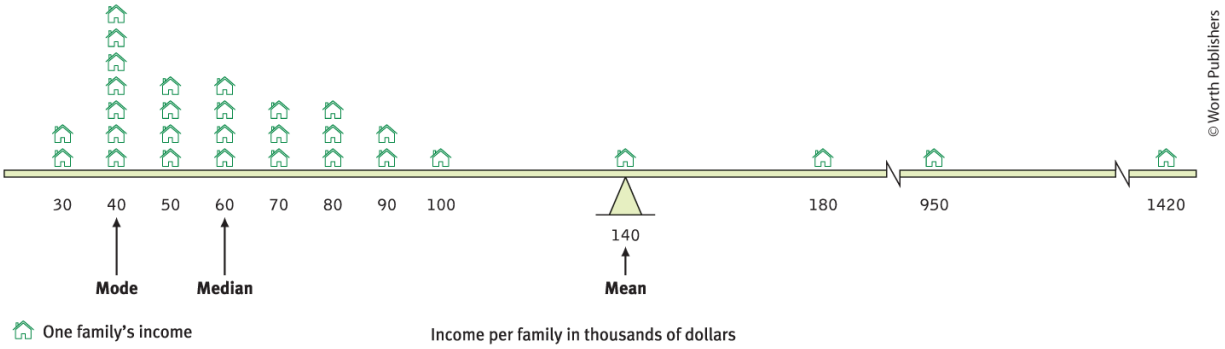


© Worth Publishers

The illustration shows five rows, with each constituting a red dot, a red skull with crossbones, a blue skull with crossbones, and 17 blue dots. The five red dots along with five red skulls with crossbones are labeled, 10 unvaccinated. The five red skulls with crossbones are labeled, *half* of unvaccinated people die. The five blue skulls with crossbones along with 85 blue dots are labeled, 90 vaccinated. The five red skulls with crossbones are labeled, Half of unvaccinated people die. The five blue skulls with crossbones are labeled, 5 "breakthrough" cases; 94.5 percent unharmed.

Return to FIGURE 3.1 Statistical literacy for vaccines

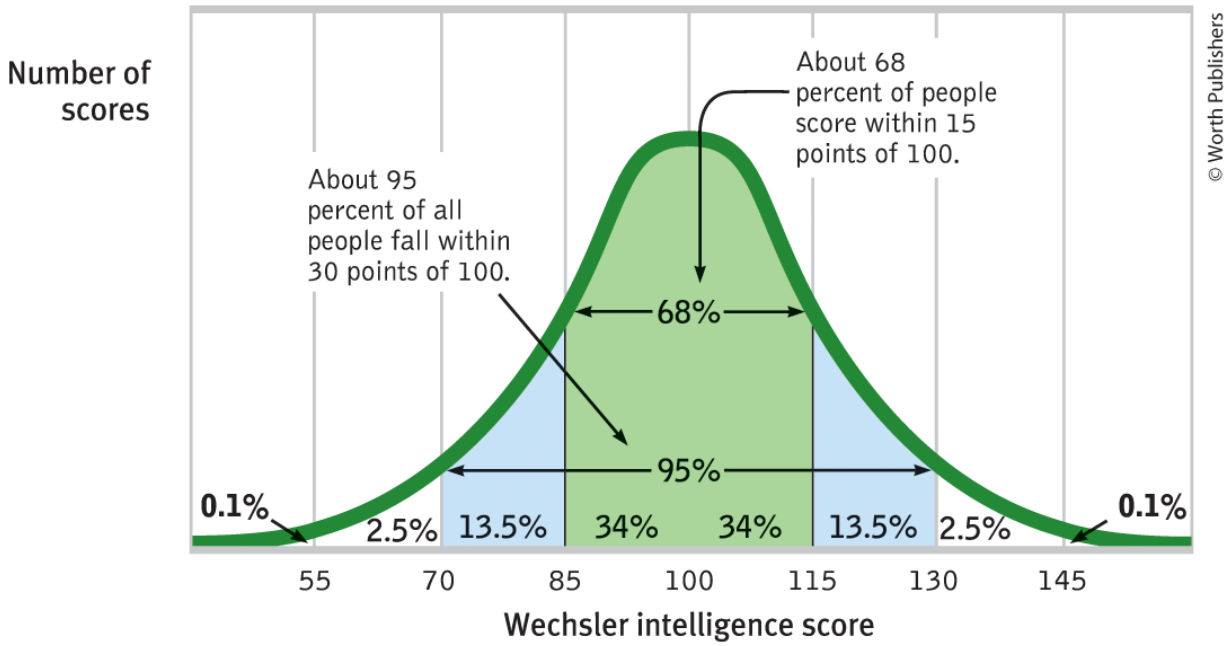
Extended description for FIGURE 3.2 Read the scale labels



The horizontal axis of both graphs represents the brand of truck and is labeled Our brand, Brand X, Brand Y, and Brand Z. Graph (a): The vertical axis represents the percentage still functioning after 10 years and ranges from 95 to 100 percent, in increments of 1. The vertical bars descend markedly from one brand of truck to the next as follows: Our brand, 98.2 percent; Brand X, 97.5 percent; Brand Y, 96.5; and Brand Z, 95.2 percent. Graph (b): The vertical axis represents the percentage still functioning after 10 years and ranges from 0 to 100, in increments of 10. The data is similar, but the vertical bars appear to be roughly equivalent from one brand of

truck to the next, with minimal difference between them. All data are approximate.

Return to FIGURE 3.2 Read the scale labels



Extended description for FIGURE 3.3 A skewed distribution

The horizontal axis is labeled as Income per family in thousands of dollars. Points marked on the line are 30, 40 (Mode), 50, 60 (Median), 70, 80, 90, 100, 140 (Mean), 180, 950, and 1420. Point 140 (mean) lies on the fulcrum of the balance scale. Illustration of houses plotted above the values on the horizontal axis each represents one family's income. The data are as follows: 30 has 2 houses, 40 (Mode) has 7 houses, 50 has 4 houses, 60 (Median) has 4 houses, 70 has 3 houses, 80 has 3 houses, 90 has 2 houses, 100 has 1 house, 140 (Mean) has 1 house, 180 has 1 house, 950 has 1 house, and 1420 has 1 house.

Return to FIGURE 3.3 A skewed distribution

Extended description for FIGURE 3.4 The normal curve

The graph shows a bell-shaped curve with different areas indicated with colors and percentages. The horizontal axis depicts the Wechsler intelligence score and ranges from 40 to 160, in increments of 15. The vertical axis represents the number of scores. The percentages of people who fall within different score ranges are presented as follows: Below 55 score, 0.1 percent; 55 to 70 score, 2.5 percent; 70 to 85 score, 13.5 percent; 85 to 100 score, 34 percent; 100 to 115 score, 34 percent; 115 to 130 score, 13.5 percent; 130 to 145 score, 2.5 percent; and above 145 score, 0.1 percent. A text pointing to the area under the curve from 85 to 115 score reads, About 68

percent of all people fall within 15 points of 100. Text pointing to the area under the curve from 70 to 130 score reads, About 95 percent of all people fall within 30 points of 100.

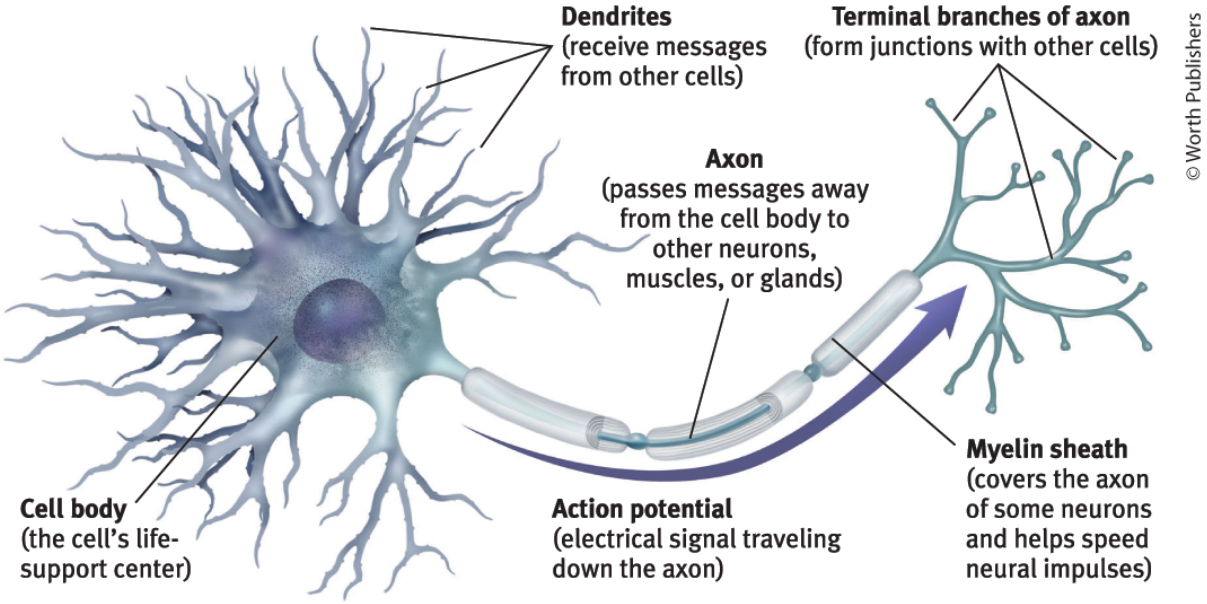
Extended description for FIGURE 4.1 A wrongheaded theory

a: Bettmann/Getty Images
© Worth Publishers



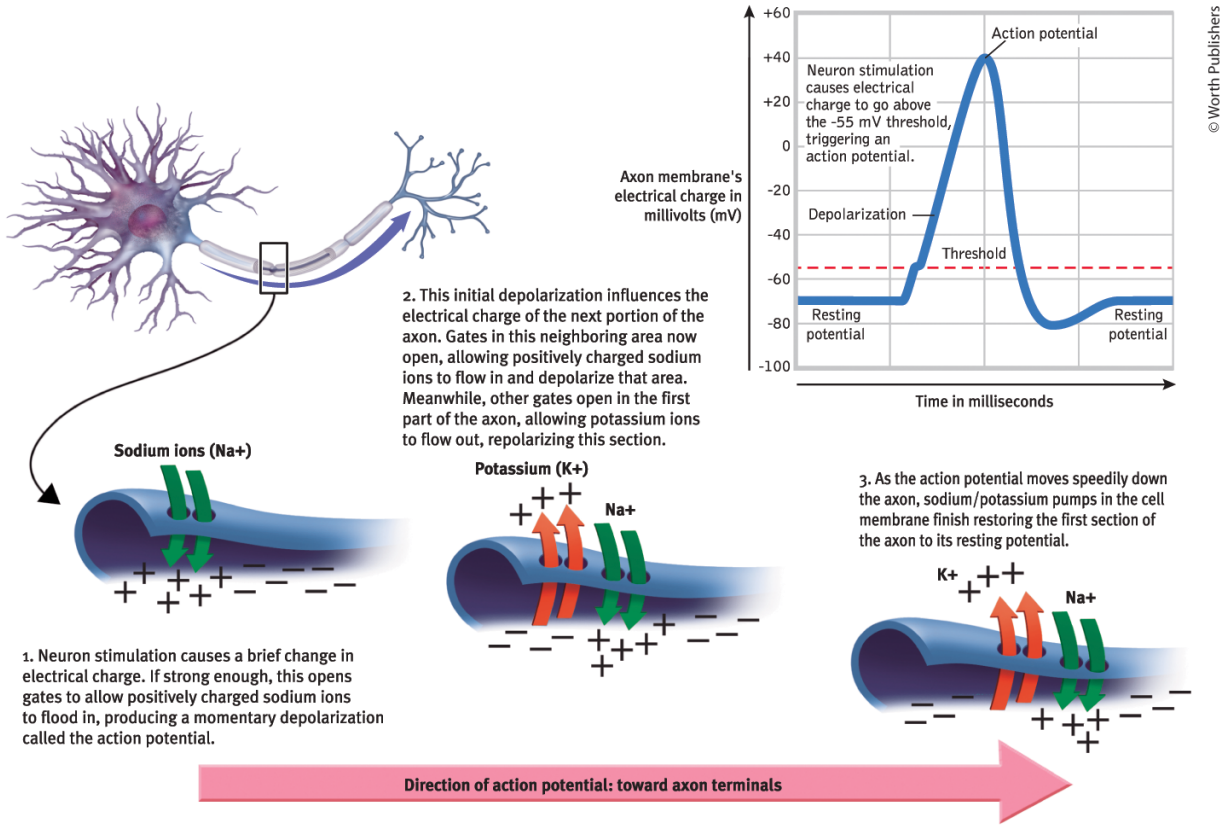
(a) Franz Gall's speculations on what the functions of the brain are based on the bumps in the head. The illustration shows a rear area marked Domestic and above it an area labeled Aspiring. Surrounding the ear is a section labeled Animal, and directly above this, the side of the head, is marked Self Perfecting. The top of the head is an area marked Moral, in front of this is a region called Reflectives, and at the front is a section called Perceptives. Within each section are a variety of other terms related to the title of that

section. For example, the section marked Moral has smaller areas with terms like benevolence and veneration. Each larger section has several such smaller areas.

(b) The illustration shows which part of the brain control which function. The bottom is an area marked arousal, and to the left and slightly higher is a section marked coordination. To the left of that is vision, and above that is a section called visual processing. Above that to the lower right is recognition, and to the upper right is comprehension. Above that, near the top back of the brain, is spatial awareness, and above this is movement. In the center of the brain is sound, and just above this is touch. In the front top of the brain are several sections, which start with planning and moving, clockwise go to thinking, judging, feeling, and taste. Just behind the eyes is smell, and above that to the left is speech. Near the ears are two areas marked emotion and memory.

Return to FIGURE 4.1 A wrongheaded theory

Extended description for FIGURE 4.2 A motor neuron



The illustration shows the cell body on the left and identifies it as the cell's life-support center. Bushy fibers branching from the cell body are labeled dendrites that receive messages from other cells. A single lengthy fiber from the cell body is identified as the axon that passes messages away from the cell body to other neurons, muscles, or glands. A fatty tissue insulating the axon is labeled myelin sheath. It covers the axon of some neurons and helps speed neural impulses. Fibers branching at the end of the axons are labeled terminal branches of axon that form junctions with other cells. An arrow pointing from the cell body to the terminal branches of axon

indicates the direction of action potential (electrical signal traveling down the axon).

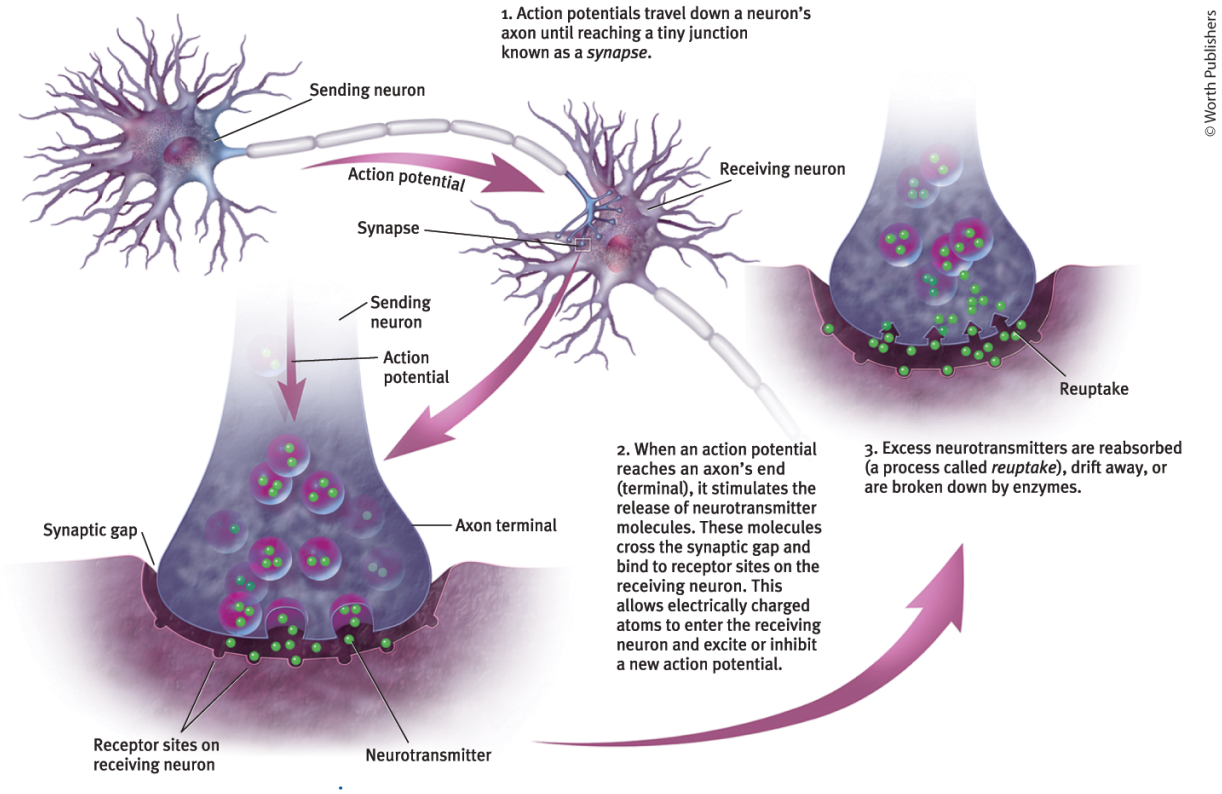
Return to FIGURE 4.2 A motor neuron

Extended description for FIGURE 4.4 Action potential

The illustration depicts the direction of the action potential toward axon terminals in three sections. A diagrammatic representation of a neuron, with three magnified sectional views of the junction between two axons, is depicted below; the first cylindrical section highlights the entry of **sodium ions**. Accompanying text reads, 1. Neuron stimulation causes a brief change in electrical charge. If strong enough, this opens gates to allow positively charged sodium

ions to flood in, producing a momentary depolarization called the action potential.

The second section shows the entry of **sodium ions** and exit of **potassium ions**. Accompanying text reads, 2. This initial depolarization influences the electrical charge of the next portion of the axon. Gates in this neighboring area now open, allowing positively charged sodium ions to flow in and depolarize that area. Meanwhile, other gates open in the first part of the axon, allowing potassium ions to flow out, repolarizing this section.



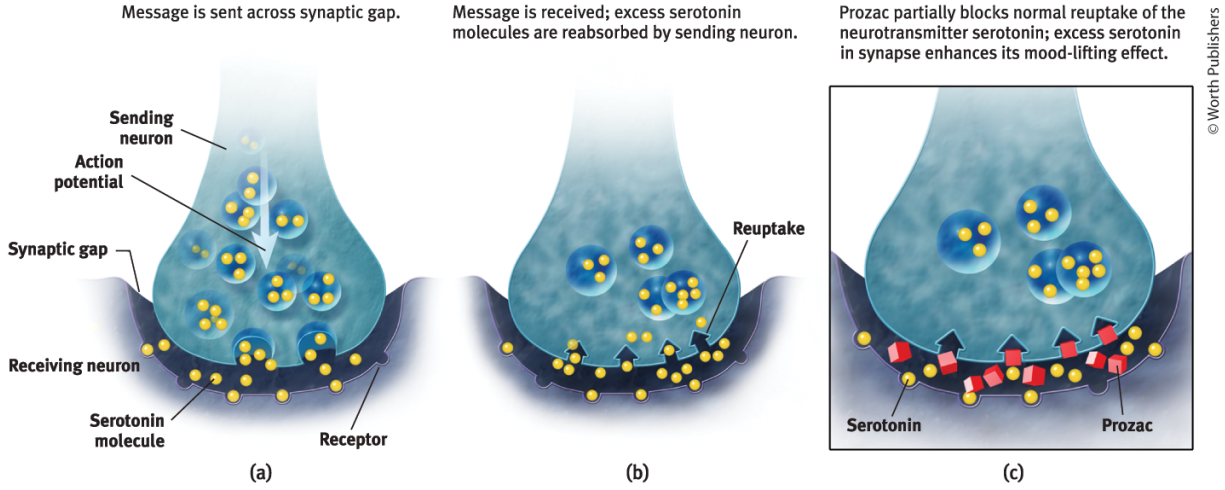
The third section shows the entry of **sodium ions** and exit of **potassium ions**. Accompanying text reads, 3. As the action potential moves speedily down the axon, sodium/potassium pumps in the cell membrane finish restoring the first section of the axon to its resting potential.

The graph plots Axon membrane's electrical charge in millivolts (m V) ranging from negative 100 to positive 60 on the vertical axis against Time in milliseconds on the horizontal axis. The graph shows a short horizontal line beginning at negative 70 (Resting potential), which suddenly increases to positive 40 (Action potential). Text reads, Neuron stimulation causes electrical charge to go above the negative 55 millivolts threshold, triggering an action potential. The curve next declines to negative 80 and then increases slightly to negative 70 (Resting potential). A horizontal straight

dashed line beginning slightly above negative 55 is labeled as “Threshold.” All data are approximate.

Return to FIGURE 4.4 Action potential

Extended description for FIGURE 4.5 How neurons communicate

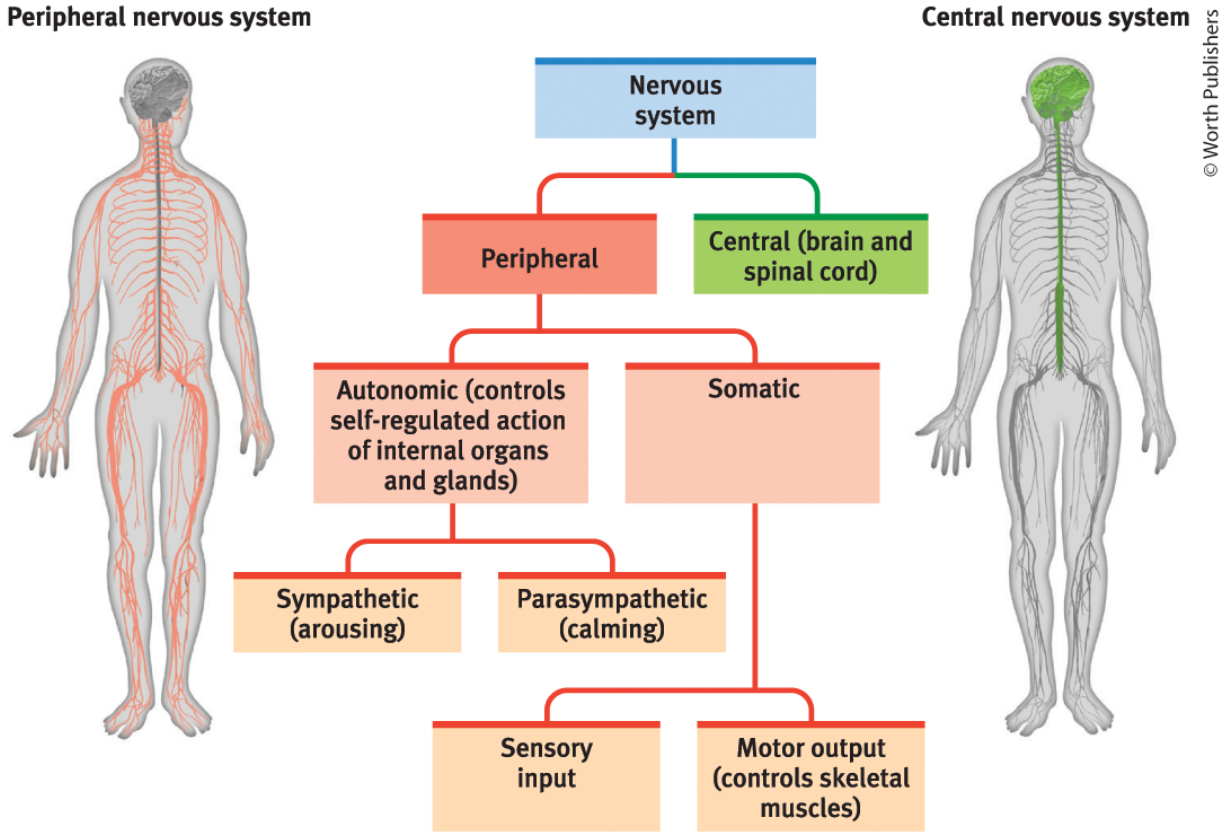


The illustration shows a sending neuron delivering an action potential to a receiving neuron. Accompanying text reads, 1. Action potentials travel down a neuron's axon until reaching a tiny junction known as a *synapse*. A zoomed-in image of the synapse shows the action potential reaching the axon terminal of the sending neuron. A synaptic gap is identified between the axon terminal of the sending neuron and the cell body of the receiving neuron. Synaptic

vesicles with neurotransmitters inside are present in the axon terminal. Neurotransmitters pass from the axon terminal of the sending neuron, through the synaptic gap, to the receptor sites on the receiving neuron. Accompanying text reads, 2. When an action potential reaches an axon's end (terminal), it stimulates the release of neurotransmitter molecules. These molecules cross the synaptic gap and bind to receptor sites on the receiving neuron. This allows electrically charged atoms to enter the receiving neuron and excite or inhibit a new action potential. A second zoomed-in image of the synapse illustrates the reuptake of the neurotransmitters. It shows the neurotransmitters in the synaptic gap being reabsorbed by the axon terminal from which they were just released. Accompanying text reads, 3. Excess neurotransmitters are reabsorbed (a process called *reuptake*), drift away, or are broken down by enzymes.

Return to FIGURE 4.5 How neurons communicate

Extended description for FIGURE 4.6 Biology of antidepressants



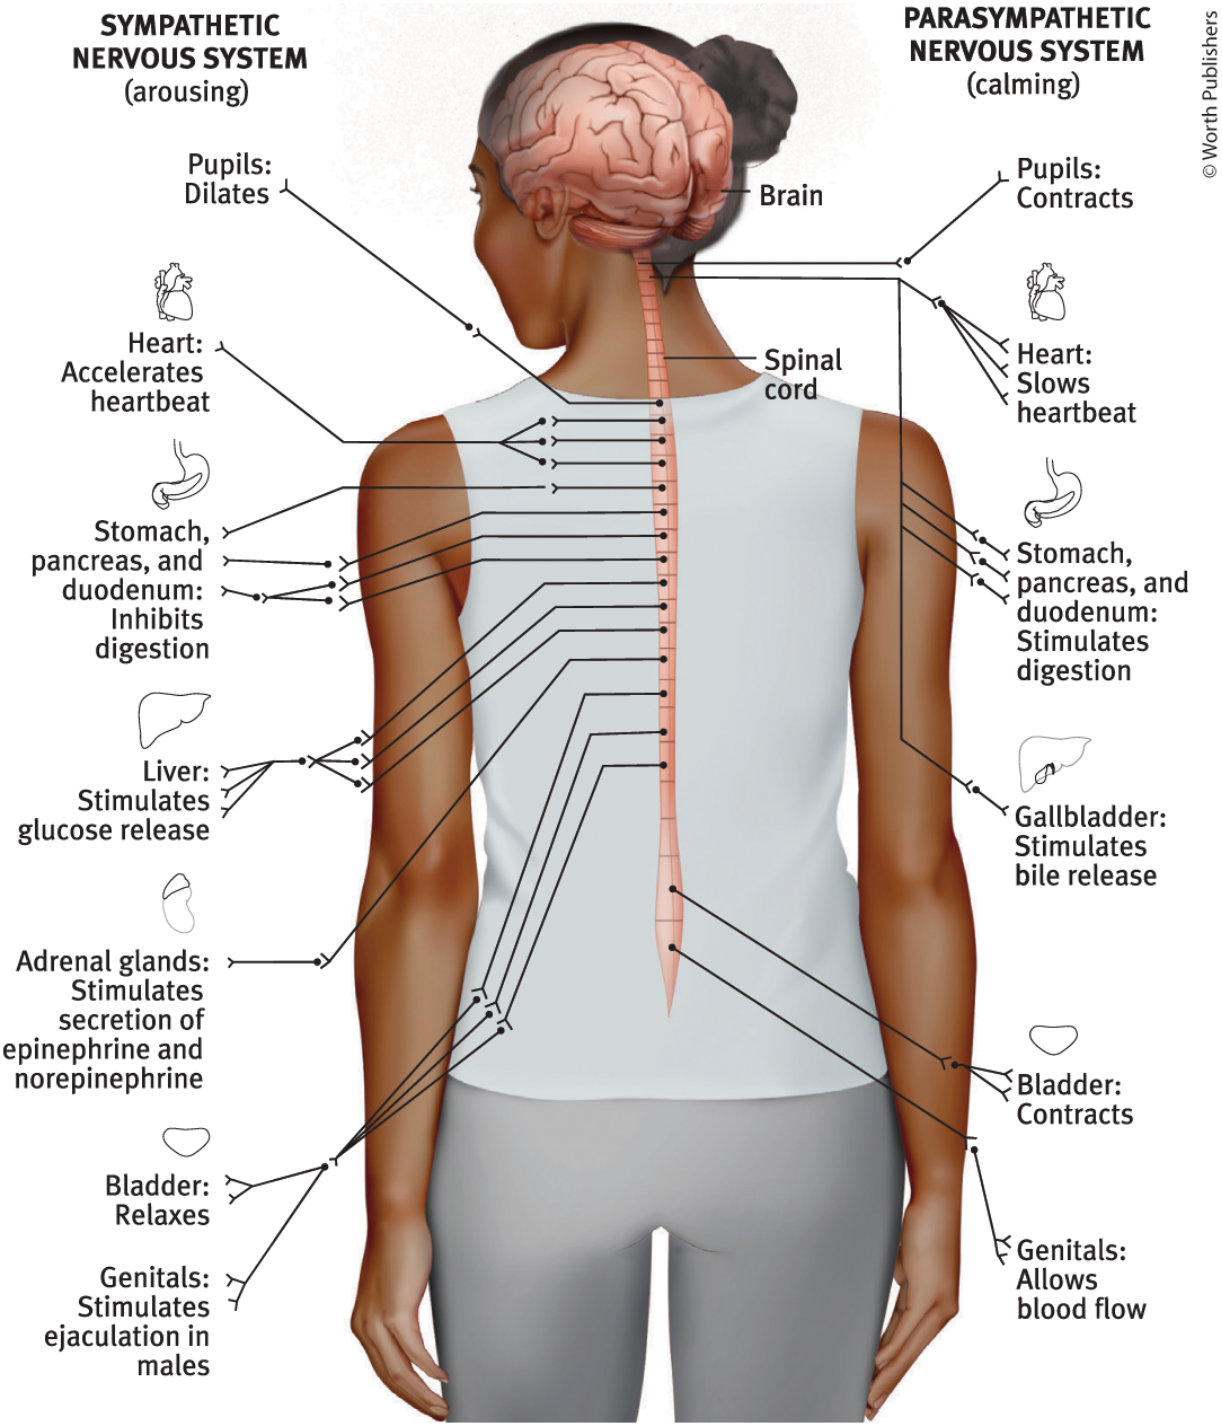
(a) An action potential from the sending neuron delivers serotonin molecules through the synaptic gap to the receptors on the receiving neuron. The following parts are labeled: sending neuron, action potential, synaptic gap, receiving neuron, serotonin molecule, and receptor. Accompanying text reads, Message is sent across synaptic gap.

(b) Serotonin molecules are absorbed by the axon terminal. The area where the molecules are reabsorbed by the sending neuron is labeled reuptake. Accompanying text reads, Message is received; excess serotonin molecules are reabsorbed by sending neuron.

(c) Prozac molecules block the reuptake sites at the axon terminal. Prozac and serotonin molecules are labeled. Accompanying text reads, Prozac partially blocks normal reuptake of the neurotransmitter serotonin, excess serotonin in synapse enhances its mood-lifting effect.

Return to FIGURE 4.6 Biology of antidepressants

Extended description for FIGURE 4.7 The functional divisions of the human nervous system



The peripheral nervous system, highlighted in red on the human figure to the left, includes nerves in the whole body except the brain and the spinal cord. The central nervous system, highlighted in green on the human figure to the right, includes the brain and the spinal cord only. The tree diagram in the middle of both human figures is as follows: The top box labeled Nervous System connects

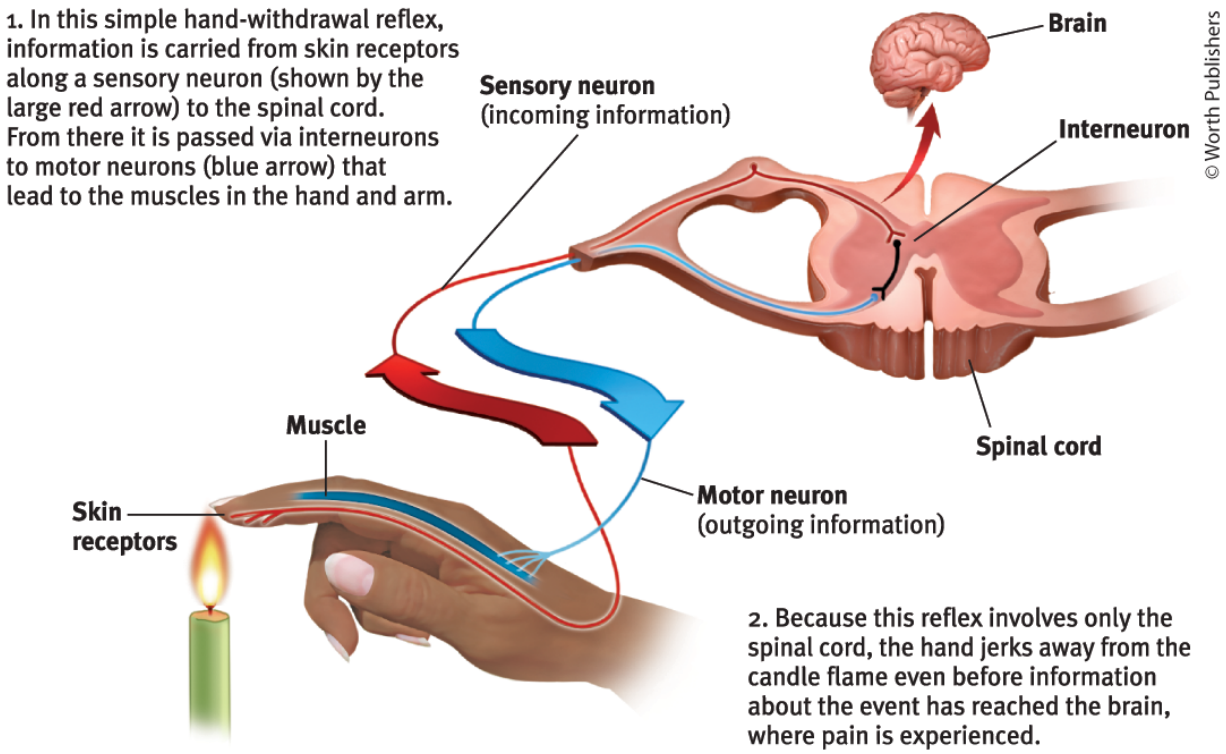
to two boxes below, the Peripheral and the Central (brain and spinal cord). The Peripheral box connects to two boxes below, the Autonomic (controls self-regulated actions of internal organs and glands) and the Somatic. The autonomic box connects to two boxes below, the Sympathetic (arousing) and the Parasympathetic (calming). The somatic box also connects to two boxes below, the Sensory input and the Motor output (controls skeletal muscles).

Return to FIGURE 4.7 The functional divisions of the human nervous system

Extended description for FIGURE 4.8 The dual functions of the autonomic nervous

system

SYMPATHETIC NERVOUS SYSTEM (arousing)
PARASYMPATHETIC NERVOUS SYSTEM (calming)
Pupils: Dilates
Brain
Pupils: Contracts
Heart: Accelerates heartbeat
Spinal cord
Heart: Slows heartbeat
Stomach, pancreas, and duodenum: Inhibits digestion
Stomach, pancreas, and duodenum: Stimulates digestion
Liver: Stimulates glucose release
Gallbladder: Stimulates bile release
Adrenal glands: Stimulates secretion of epinephrine and norepinephrine
Bladder: Contracts
Bladder: Relaxes
Genitals: Stimulates ejaculation in males
Genitals: Allows blood flow
© Worth Publishers



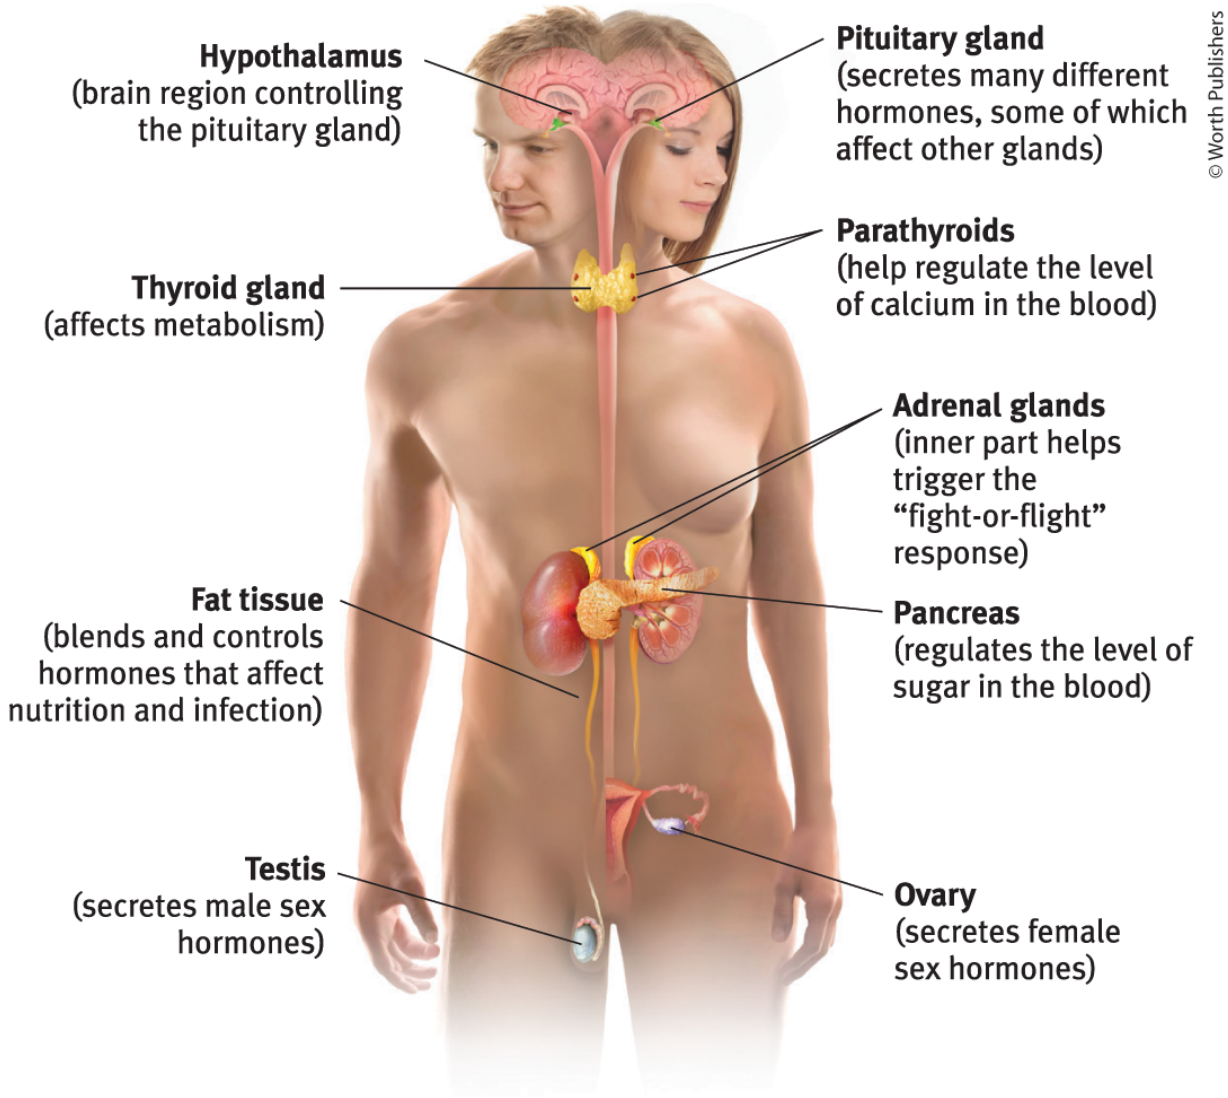
The illustration shows the posterior view of a woman with her brain and spine highlighted. To the left is the sympathetic nervous system (arousing) and to the right is the parasympathetic nervous system (calming). The functions of each type of system are depicted by pointing at the area of the spine where they are controlled. Each function is accompanied by a rudimentary diagram of the body part controlled.

The functions of the sympathetic nervous system are as follows. Pupils: Dilate (single vertebra near shoulders); Heart: Accelerates heartbeat (next 3 vertebrae); Stomach, Pancreas, and Duodenum: inhibit digestion (next 4 vertebrae); Liver: stimulates glucose release (next 3 vertebrae); Adrenal glands: stimulate secretion of epinephrine and norepinephrine (next vertebra down); and Bladder: Relaxes and Genitals: stimulates ejaculation in males (next 3 vertebrae).

The functions of the parasympathetic nervous system are as follows. Pupils: contract (near top of spinal cord); Next functions all occur just below the top of the spinal cord: Heart, slows heartbeat; stomach, pancreas, and duodenum, stimulate digestion; gallbladder, stimulates bile release; Next functions both occur near the bottom of the spinal cord: Bladder, contracts; and genitals, allows blood flow.

Return to FIGURE 4.8 The dual functions of the autonomic nervous system

Extended description for FIGURE 4.9 A simple reflex

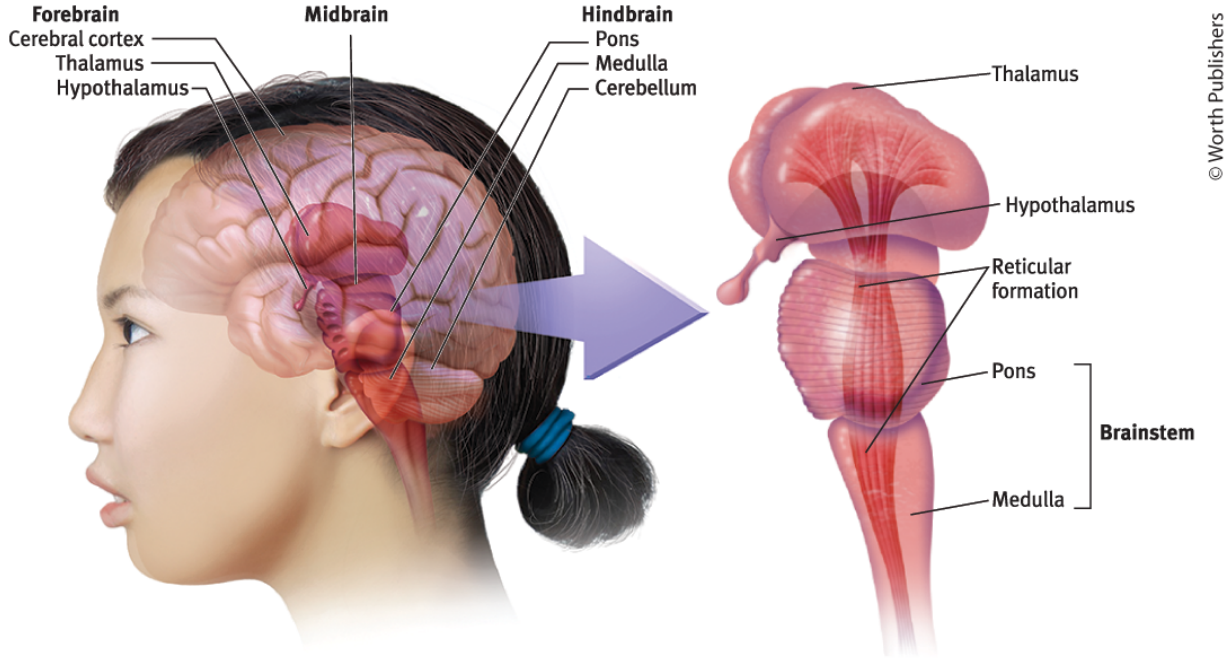


The illustration shows a finger almost touching a flame, a cross-section of the spinal cord, and a lateral view of the brain. A red arrow labeled, sensory neuron (incoming information), connects skin receptors on the finger to the spinal cord. An interneuron connects the sensory neuron to the motor neuron in the spinal cord. The information is passed from the spinal cord to the brain. A blue arrow labeled motor neuron (outgoing information) connects the spinal cord to the muscles in the finger. Text reads, 1. In this simple

hand-withdrawal reflex, information is carried from skin receptors along a sensory neuron (shown by the large red arrow) to the spinal cord. From there it is passed via interneurons to motor neurons (blue arrow) that lead to the muscles in the hand and arm. 2. Because this reflex involves only the spinal cord, the hand jerks away from the candle flame even before information about the event has reached the brain, where pain is experienced.

Return to FIGURE 4.9 A simple reflex

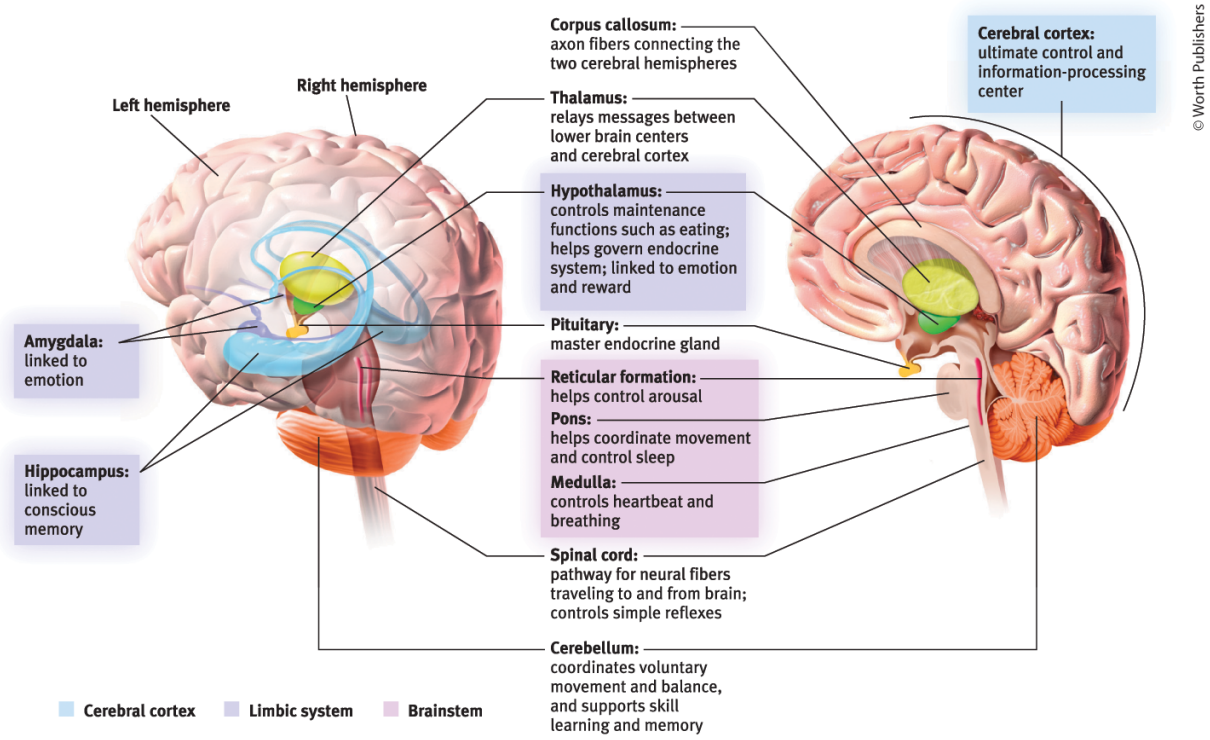
Extended description for FIGURE 4.10 The endocrine system



The **hypothalamus** (brain region controlling the pituitary gland) and the **pituitary gland** (secretes many different hormones, some of

which affect other glands) are labeled in the brain. The **thyroid gland** (affects metabolism) and the **parathyroids** (help regulate the level of calcium in the blood) are labeled on the lower neck. The **adrenal glands** (inner part helps trigger the "fight-or-flight" response) and the **pancreas** (regulates the level of sugar in the blood) are labeled in the upper abdomen. **Fat tissue** (blends and controls hormones that affect nutrition and infection) are labeled in the lower abdomen. The **testis** (secretes male sex hormones) is labeled on the male body, and the **ovary** (secretes female sex hormones) is labeled on the female body.

Return to FIGURE 4.10 The endocrine system



Extended description for FIGURE 6.1 Brain divisions: forebrain, midbrain, hindbrain

The illustration shows the side profile of a human head highlighting the brain. In the brain, the anterior region is labeled forebrain and includes cerebral cortex, thalamus, and hypothalamus; the middle region is labeled midbrain; and the posterior region is labeled hindbrain and includes pons, medulla, and cerebellum. An enlarged view shows a brainstem with pons situated above the medulla. The thalamus lies above the brainstem and has hypothalamus extending from it. The reticular formation is present in the pons and medulla.

Return to FIGURE 6.1 Brain divisions: forebrain, midbrain, hindbrain

Extended description for FIGURE 6.6 Brain structures and their functions

The illustration on the left shows the lateral view of a brain constituting the left and right hemispheres. The illustration on the right shows the inner lateral view of the right hemisphere. The common structures labeled are as follows along with their functions.

Thalamus: relays messages between lower brain centers and cerebral cortex.

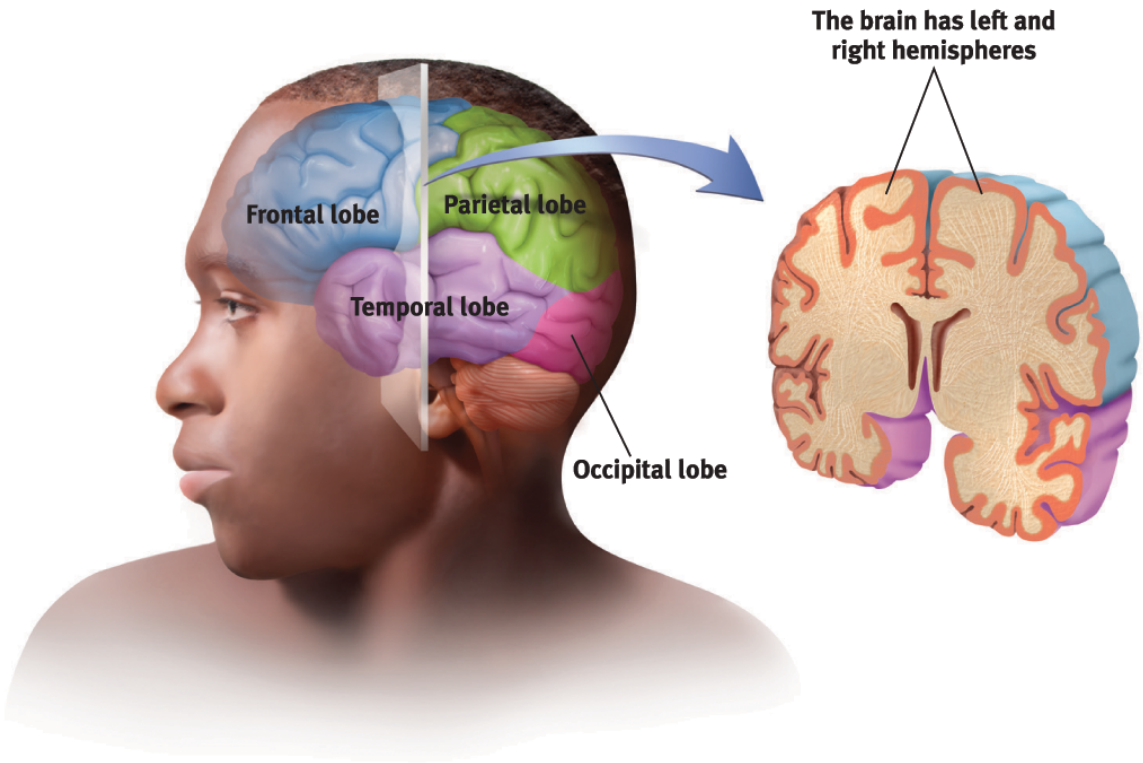
Hypothalamus (Limbic system): controls maintenance functions such as eating; helps govern endocrine system; linked to emotion and reward.

Pituitary: master endocrine gland.

Reticular formation (Brainstem): helps control arousal.

Pons (Brainstem): helps coordinate movement and control sleep.

Medulla (Brainstem): controls heartbeat and breathing.



Spinal cord: pathway for neural fibers traveling to and from the brain; controls simple reflexes.

Cerebellum: coordinates voluntary movement and balance, and supports skill learning and memories.

The parts labeled in left illustration also include Amygdala (Limbic system): linked to emotion; and Hippocampus (Limbic system): linked to conscious memory. The parts labeled in left illustration also include Corpus callosum: axon fibers connecting the two cerebral hemispheres; and Cerebral cortex: Ultimate control and information-processing center.

Return to FIGURE 6.6 Brain structures and their functions

Extended description for FIGURE 6.7 The cortex and its basic subdivisions

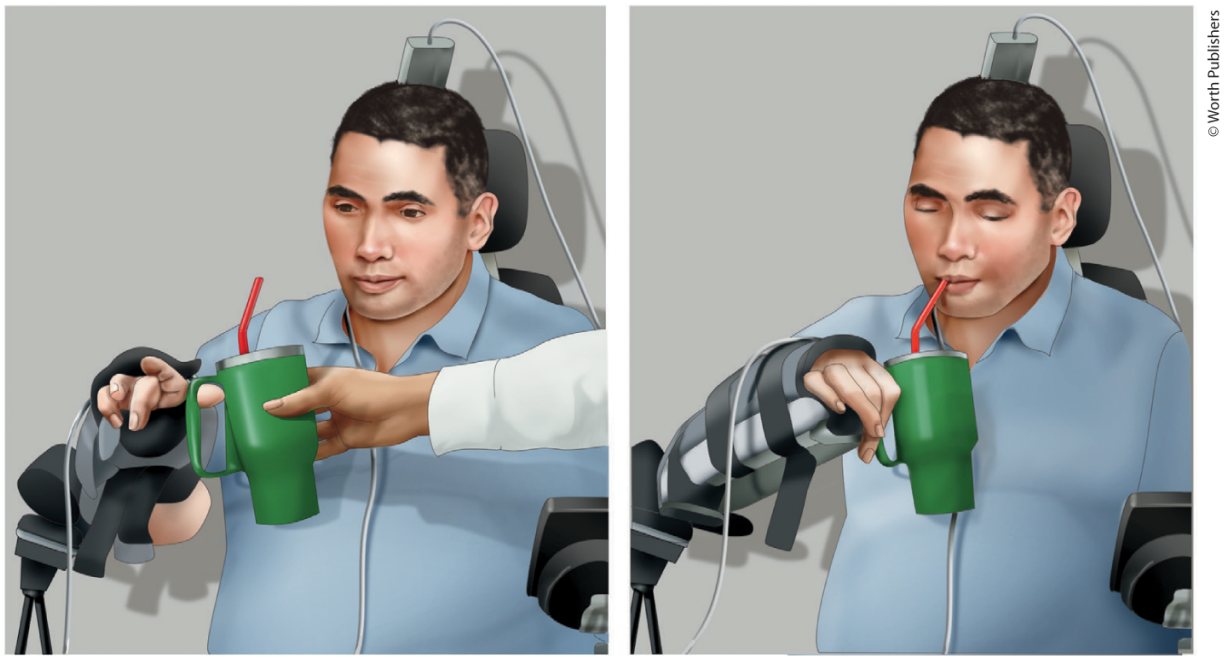
The frontal lobe is highlighted in blue and is located at the front of the brain behind the forehead. The parietal lobe is highlighted in green and located at the top back of the brain. The temporal lobe is highlighted in purple and located below the two regions previously mentioned and centered behind the ear. The occipital lobe is highlighted in pink and located at the bottom rear of the brain. An enlarged view shows a cross-section of the brain, through the

middle, from top to bottom. This cross-section shows that the brain has largely symmetric left and right hemispheres.

Return to FIGURE 6.7 The cortex and its basic subdivisions

Extended description for FIGURE 6.8 Motor cortex and somatosensory cortex tissue devoted to each body part



The illustration on the left depicts the lateral view of brain with the motor cortex and coronal plane dividing the cortex of the frontal lobe highlighted. Text above the illustration reads, Output: motor cortex (right hemisphere section controls the body's left side). The parts controlled by the motor cortex are labeled as follows: swallowing, tongue, jaw, lips, face, eyebrow, neck, thumb, fingers, hand, wrist, elbow, arm, shoulder, torso, hip, knee, ankle, and toes.

The illustration on the right depicts the lateral view of brain with the somatosensory cortex and a coronal plane dividing the cortex of the frontal lobe highlighted. Text above the illustration reads, Input: somatosensory cortex (left hemisphere section receives input from the body's right side). The parts controlled by the somatosensory cortex are labeled as follows: intra-abdominal, pharynx, tongue, jaw, lips, face, nose, eye, thumb, fingers, hand, forearm, elbow, arm, head, neck, torso, hip, knee, leg, foot, toes, and genitals.

The first illustration shows the man with the electronic device implanted into his head, and his right arm is in a control device. A person's hand is handing the man a coffee tumbler with a straw in it. The second illustration shows the man drinking from the straw as his hand has slowed around the handle of the coffee tumbler and moved it closer to his face.

Return to FIGURE 6.9 Brain-machine interaction

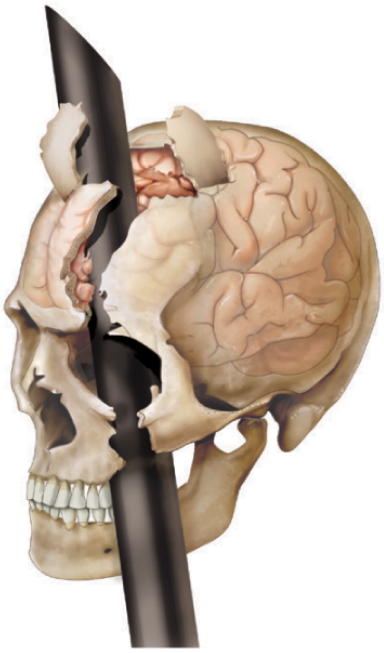
Extended description for Do we use only 10 percent of our brain?

© Worth Publishers

Text on the top reads, **Thinking Critically About: Do We Use Only 10 Percent of Our Brain?**

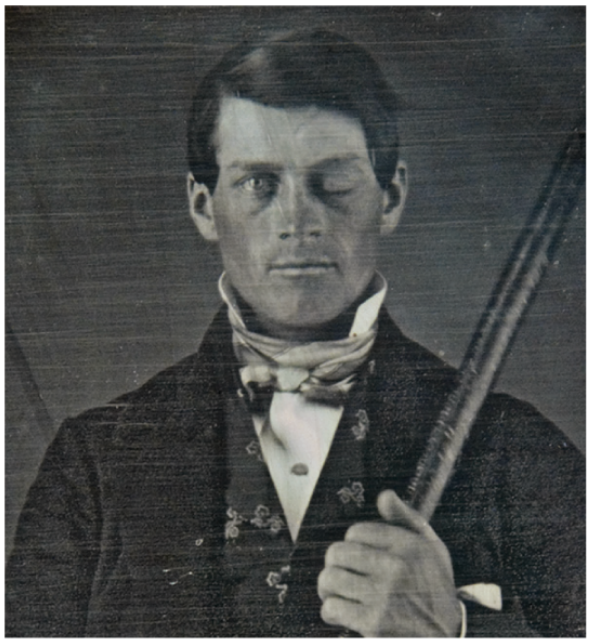
The four steps of the infographic are as follows:

1: Electrically probing an association area leads to no observable response. The illustration shows a human brain being probed and monitored. A computer screen has an image of the brain with a question mark overlaid on it.



2. This vast association area “silence” has led to the false claims that we really use only **10 percent of our brain** dash “one of the hardiest weeds in the garden of psychology.“ (McBurney, 19 96, p. 44)

3. Is there really a **90 percent** chance that a bullet to your brain would land in an unused area? The illustration shows a bullet shot toward a brain. The answer is no.



4. Brain-damaged animals and humans bear witness: Association areas interpret, integrate, and act on sensory information and link it with stored memories. More intelligent animals have larger association areas. The illustration shows the motor areas, association areas, and somatosensory areas in the brains of a rat, a cat, a chimpanzee, and a human.

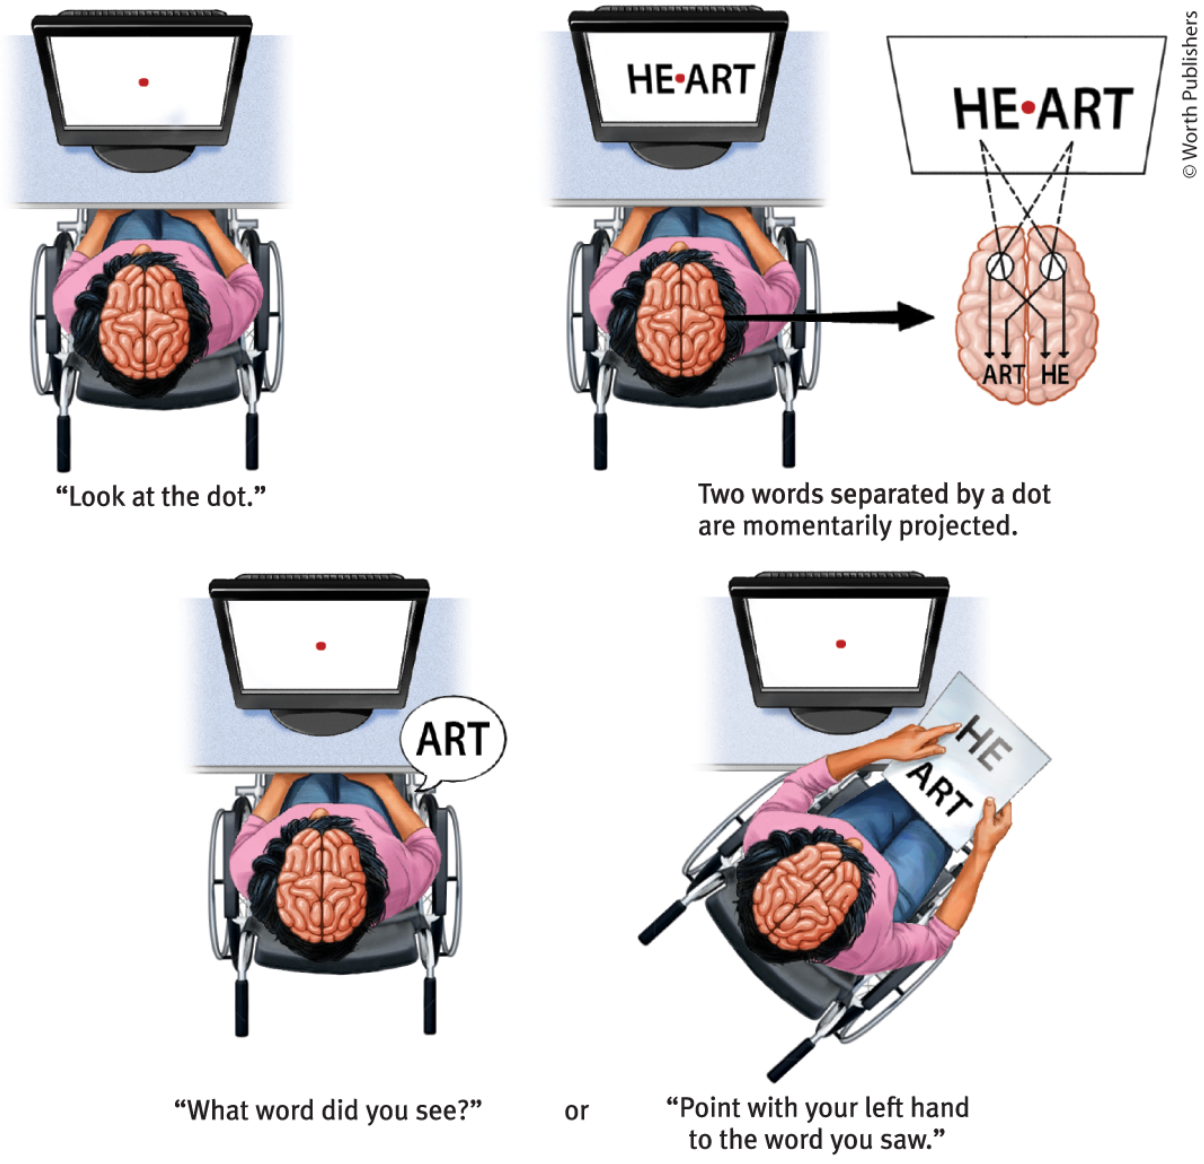
The digital reconstruction shows the rod shattering the skull on the left side of the face, through the cheek and cheekbone, behind the eye socket, through the forehead, and shattering and emerging at the top of the head, where the fracture appears to be most severe. The photo shows Phineas Gage holding the rod that pierced through his head. His left eye is closed, and he has a scar across his forehead and left cheek.

Return to FIGURE 6.12 A blast from the past

Extended description for FIGURE 7.3 The

information highway from eye to brain



© Worth Publishers

The illustration shows a pencil in the left visual field and an apple in the right visual field. The information highways traveling to the brain are highlighted in blue, for the left visual field, and red, for the right visual field. Each eye receives information from both fields. Half of the information each eye receives comes from the left visual field, and half from the right. When the optic nerves meet, called the optic chiasm, information from the left visual field is regrouped and travels to the visual area of the right hemisphere, while the information from the right visual field regroups and travels to the visual area of the left hemisphere. As a result, the apple which was in the right visual field is reproduced in the left hemisphere, and the pencil which was initially in the left visual field is represented in the right hemisphere. The diagram also highlights that speech is on the left side of the brain. The corpus callosum joins the two hemispheres of the brain.

Return to FIGURE 7.3 The information highway from eye to brain

Extended description for FIGURE 7.4 One skull, two minds

The illustration for an experiment on the divided brain shows the top view of a woman with both hemispheres of her brain

highlighted. Part a: The screen in front of her has a dot at the center. Accompanying text reads, Look at the dot. Part b: The image is similar to part a but instead of a dot the word HEART appears on the screen with the dot between the letters H E and A R T. Accompanying text reads, Two words separated by a dot are momentarily projected. The diagram of the brain shows the same image on the screen with arrows going into the brain. H E, displayed on the left visual field, is reflected on the visual area of the right hemisphere, while A R T, displayed on the right visual field, is reflected on the left visual hemisphere of the brain. Part c shows two sections with the word, Or, in between. The left section shows the image similar to part a. A question reads, What word did you see? The woman replies, A R T. The right section is also similar except the woman is now sitting slightly sideways and holding a paper with the word H E on the top half and A R T on the bottom half. A question reads, Point with your left hand to the word you saw. The woman points to the word H E.

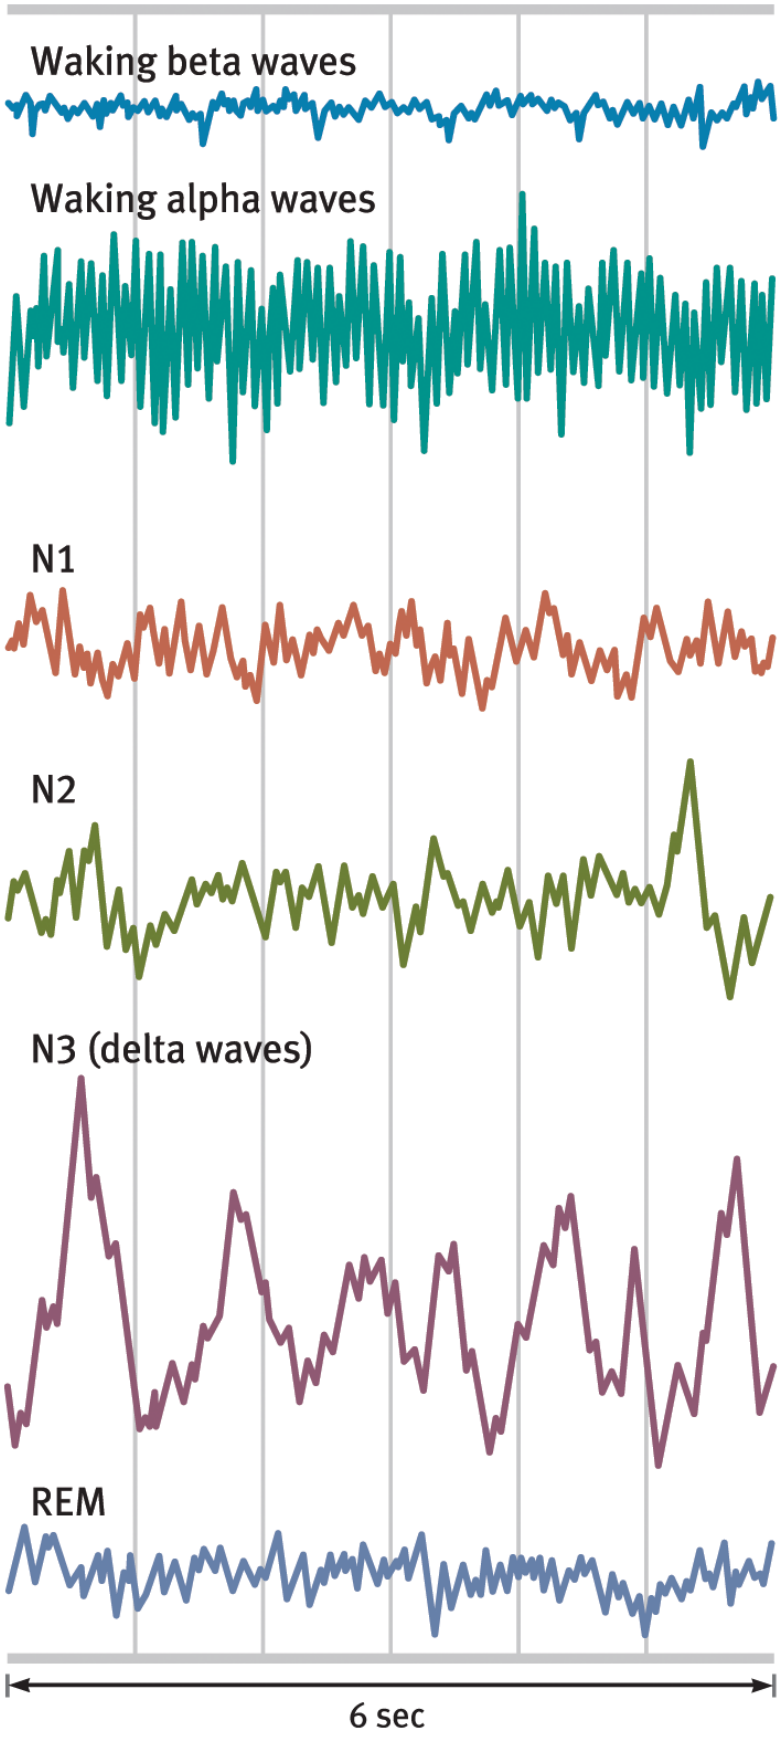
In the first panel, an elderly man gives directions to a younger man. In the second panel, construction workers, carrying a huge board, walk between these two men so that the men cannot see each other temporarily. In the third panel, the elderly man continues giving directions to a younger man who is now dressed in a differently colored jacket.

Return to FIGURE 8.4 Change blindness

Extended description for FIGURE 9.1 Measuring sleep activity

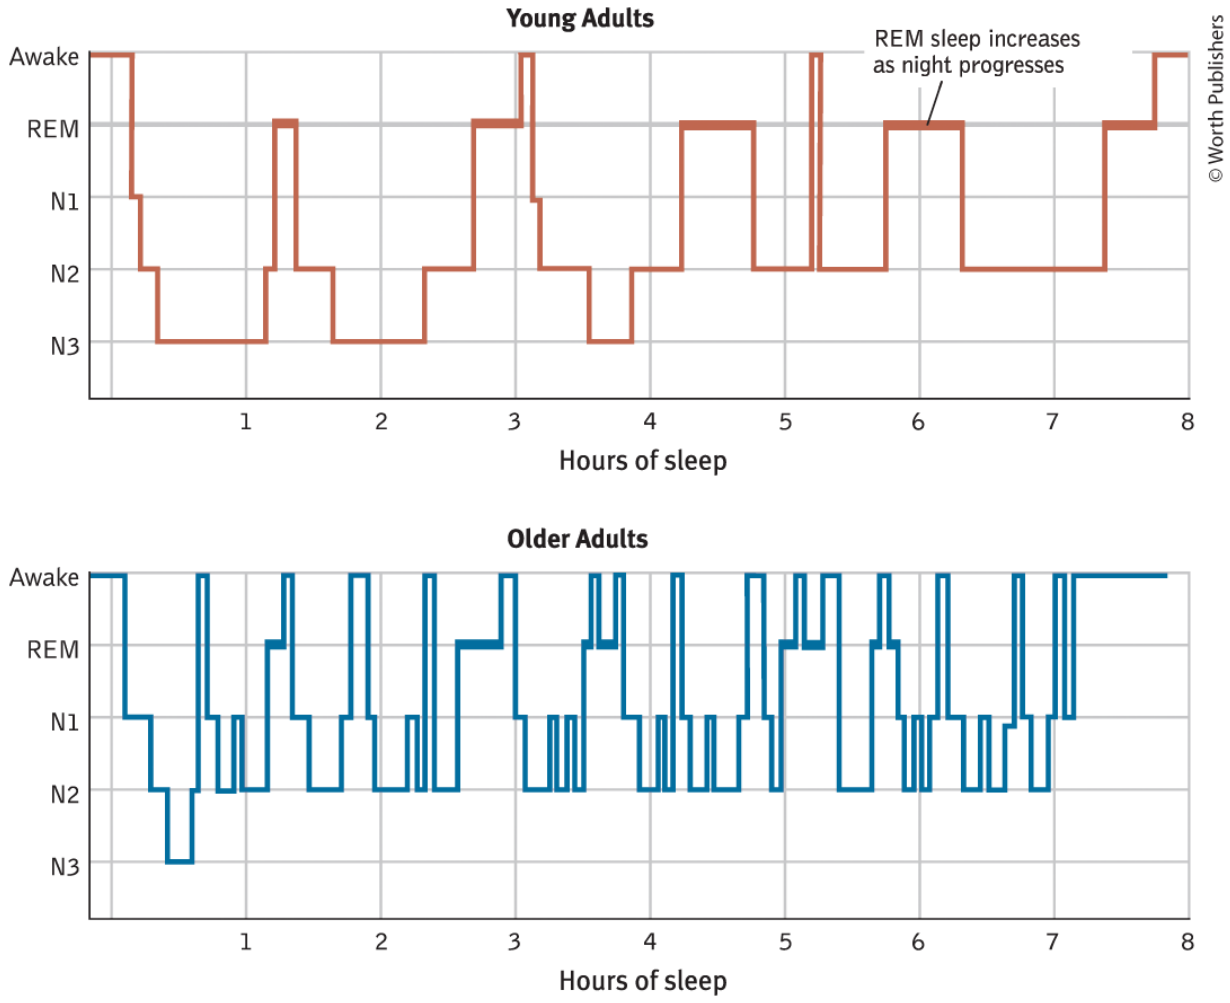


A top left illustration shows the profile of a person's head with electrodes placed on the back of the head, the outer corner of the eye, under the lower lip, and below the chin. An inferior view of the head shows the left and right eye movements, measured by placing two electrodes on the left and right temples. E M G (muscle tension) is picked up by electrodes above and below the chin. A superior view of the head shows E E G (brain waves) measured by electrodes placed on the forehead and the right temple. A photo shows a person asleep in a hospital bed with electrodes attached and monitored by a machine.

Return to FIGURE 9.1 Measuring sleep activity

Extended description for FIGURE 9.2 Brain

waves and sleep stages

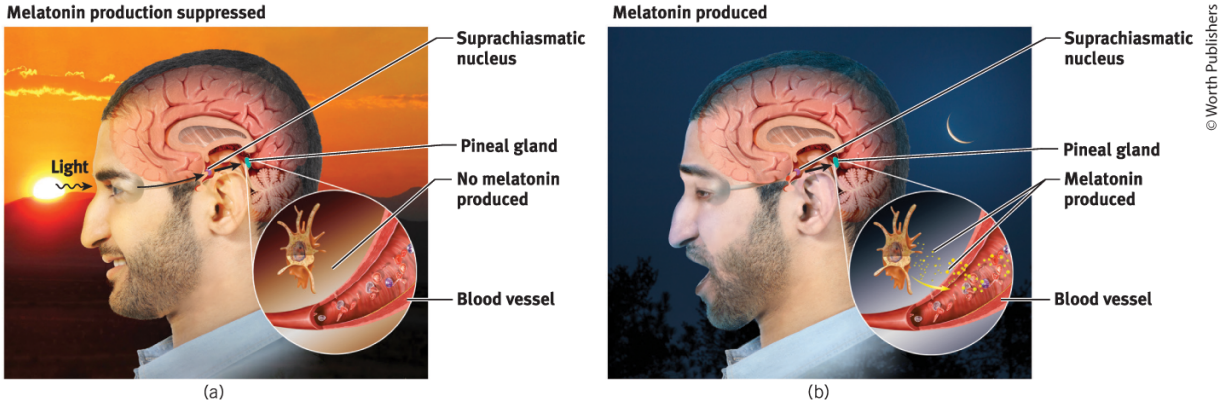


Rebecca Spencer, University of Massachusetts, assisted with this illustration.
© Worth Publishers

The six waves are depicted on the graph with time on the horizontal scale, which spans six seconds. The waking beta and waking alpha waves are regular, which differ from the slower, larger delta waves of N 3. R E M and N 1 are nearly identical. N 2 and N 3 have much higher amplitudes than do either N 1 or R E M. Similarly, the amplitude of waking alpha waves is significantly larger than that of waking beta waves.

Return to FIGURE 9.2 Brain waves and sleep stages

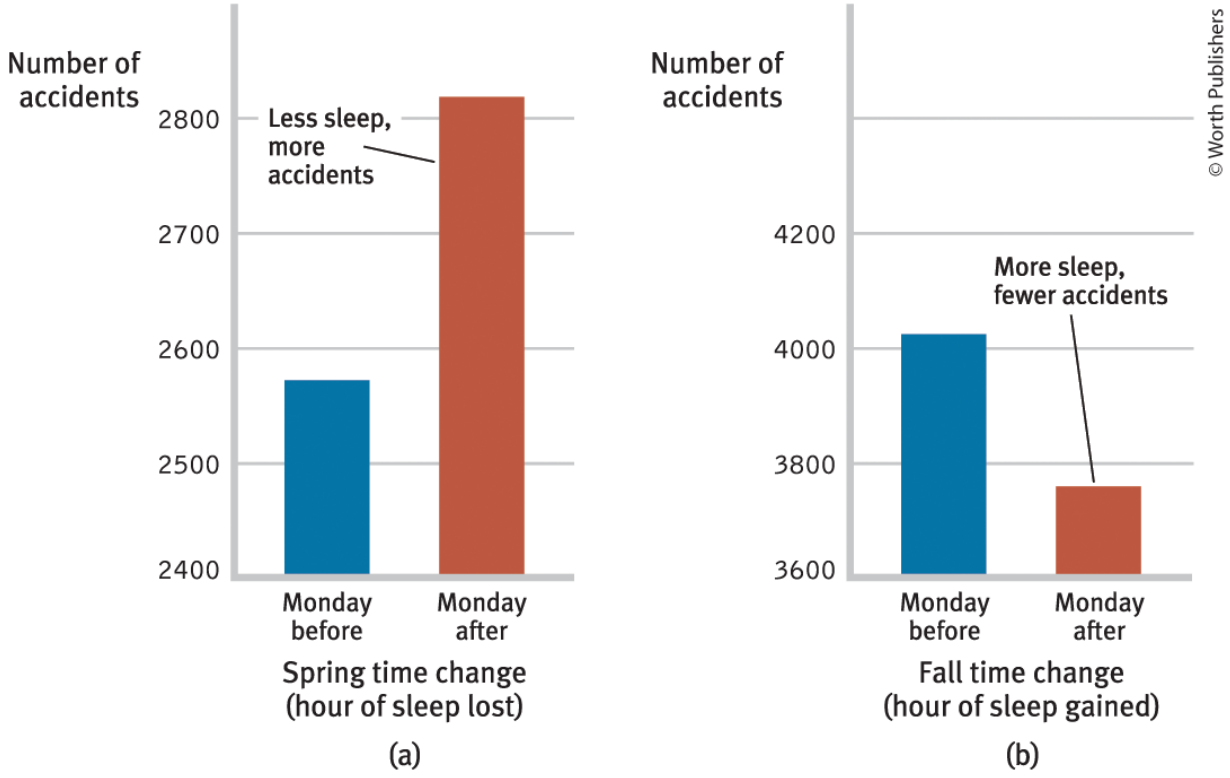
Extended description for FIGURE 9.4 The stages in a typical night's sleep



In both graphs, the horizontal axis represents hours of sleep and ranges from 0 to 8, in increments of 1; and the vertical axis is labeled N 3, N 2, N 1, R E M, and awake from bottom to top. For young adults, the graph shows that people pass through the sleep cycle

several times each night. R E M increases as the night progresses. In the first four hours of sleep, people cycle between awake and N 3, while after the fourth hour the cycle only spans between awake and N 2. For older adults, the graph reaches N 3 in the first hour of sleep and awakenings are more common. While young adults only awaken every three hours, older adults awaken as often as twice per hour. Further, each stage becomes shorter with increasing hours of sleep.

Return to FIGURE 9.4 The stages in a typical night's sleep

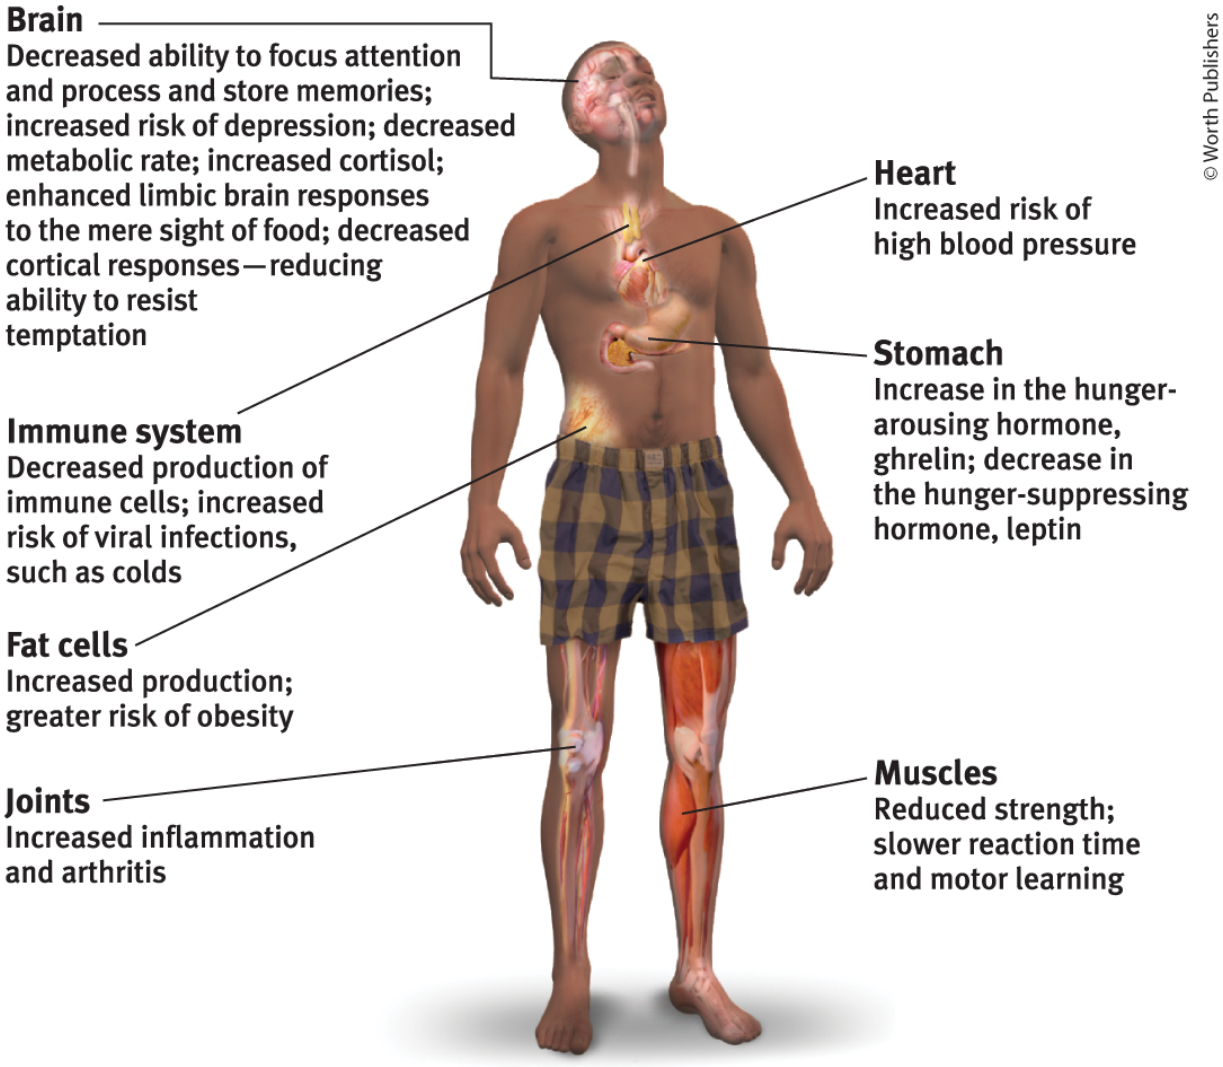


Extended description for FIGURE 9.5 The biological clock

Both parts show the lateral view of a human's head with the brain highlighted. Part a shows the man next to a setting sun. Light enters the eyes, reaches the suprachiasmatic nucleus, and then to the pineal gland. A close-up image shows the pineal gland and a nearby blood vessel. In the pineal gland, no melatonin is produced. Part b shows the man in the dark with the moon in the background. The close-up image shows the pineal gland releasing melatonin into the nearby blood vessel.

Return to FIGURE 9.5 The biological clock

Extended description for FIGURE 9.7 Less sleep equals more accidents

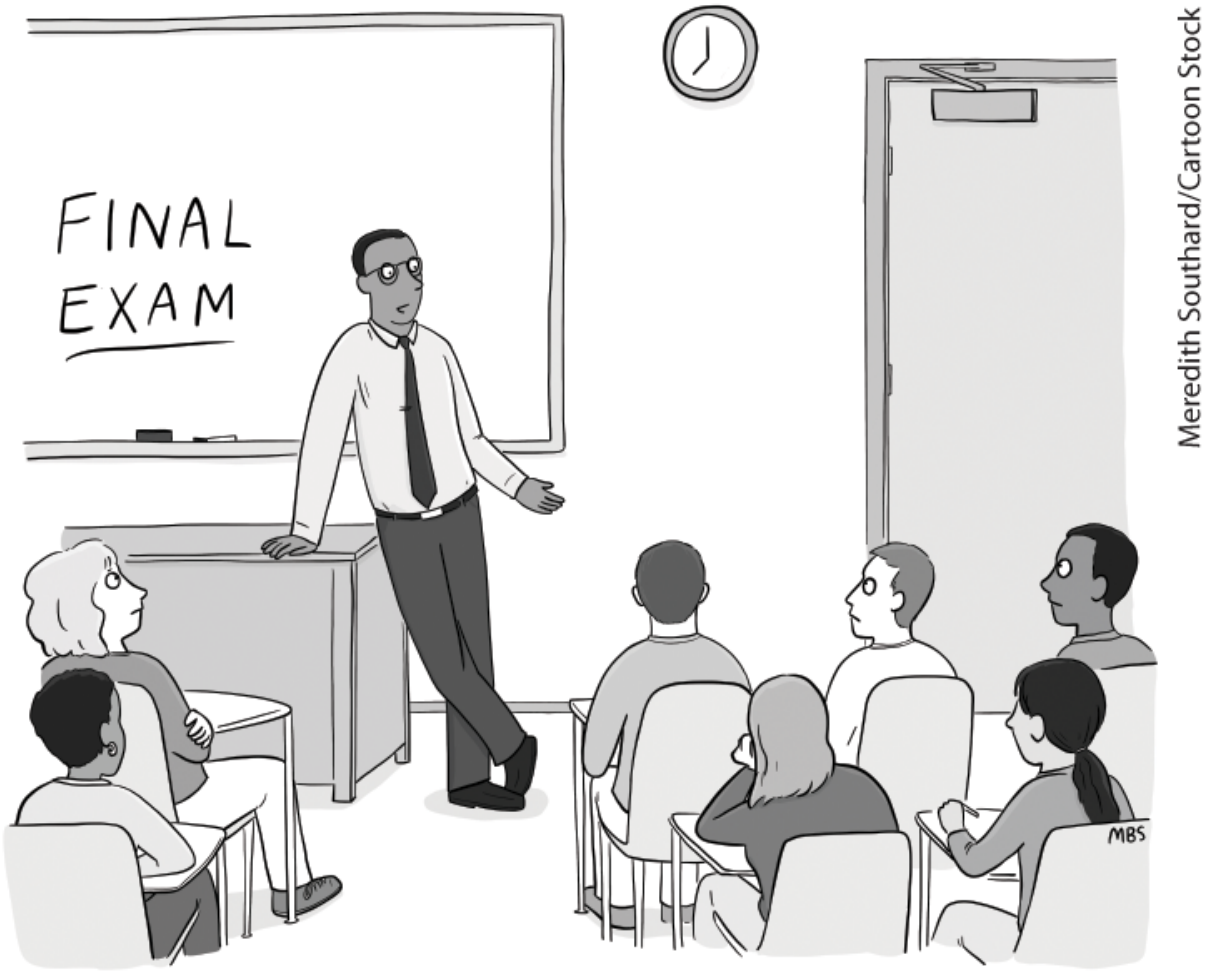


Graph A: The vertical axis shows the number of traffic accidents ranging from 2400 to 2800, in increments of 100. The horizontal axis shows the spring time change (hour of sleep lost). The data shows that on Monday before the spring time change, there were 2580 accidents; and on Monday after spring time change, there were 2820 accidents. The bar for Monday after the spring time change is labeled, Less sleep, more accidents.

Graph B: The vertical axis shows the number of traffic accidents ranging from 3600 to 4200, in increments of 200. The horizontal axis shows the fall time change (hour of sleep gained). The data shows that on Monday before the fall time change, there were 4050 accidents; and on the Monday after the fall time change, there were 3750 accidents. The bar for Monday after the fall time change is labeled, More sleep, fewer accidents. All data are approximate.

Return to FIGURE 9.7 Less sleep equals more accidents

Extended description for FIGURE 9.8 How sleep deprivation affects us



The parts labeled are as follows. **Brain:** Decreased ability to focus attention and process and store memories; increased risk of depression; decreased metabolic rate; increased cortisol; enhanced

limbic brain responses to the mere sight of food; decreased cortical responses—reducing ability to resist temptation. **Immune system:** Decreased production of immune cells; increased risk of viral infections, such as colds. **Fat cells:** Increased production; greater risk of obesity. **Joints:** Increased inflammation and arthritis. **Heart:** Increased risk of high blood pressure. **Stomach:** Increase in the hunger-arousing hormone, ghrelin, decrease in the hunger-suppressing hormone, leptin. **Muscles:** Reduced strength; slower reaction time and motor learning. Each body part and description points to the associated area on the illustration of the human.

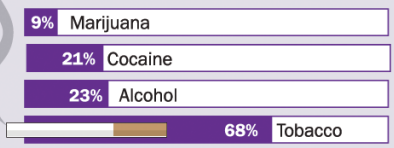
Thinking Critically About:
Tolerance and Addiction

Tolerance

With continued use of alcohol and some other drugs, users develop **tolerance** as their brain chemistry adapts to offset the drug effect (*neuroadaptation*). To experience the same effect, users require larger and larger doses, which increase the risk of becoming **addicted** and developing a *substance use disorder*.



Addiction

Caused by ever-increasing doses of most psychoactive drugs (including prescription painkillers). Prompts user to crave the drug, to continue use despite adverse consequences, and to struggle when attempting to **withdraw** from it. These behaviors suggest a substance use disorder. Once in the grip of addiction, people *want* the drug more than they *like* the drug.[1]

4% of the world's people have an alcohol use disorder.[2]

The lifetime odds of getting hooked after using various drugs:

Source: National Epidemiologic Survey on Alcohol and Related Conditions [3]

Therapy or group support, such as from Alcoholics Anonymous, may help. It also helps to believe that addictions are controllable and that people can change. Many people do voluntarily stop using addictive drugs without any treatment. "Most people who successfully quit smoking kicked the habit on their own."[4]

Behavior Addictions

Psychologists try to avoid using "addiction" to label driven, excessive behaviors such as eating, work, sex, and accumulating wealth.

Yet some behaviors can become compulsive and dysfunctional—similar to problematic alcohol and drug use.[5] Behavior addictions include *gambling disorder. Internet gaming disorder* is also now a diagnosable condition.[6] Such gamers display a consistent inability to resist logging on and staying on, even when this excessive use impairs their work and relationships. One international study of 19,000 gamers found that 1 in 3 had at least one symptom of the disorder. But fewer than 1 percent met criteria for a diagnosis.[7]

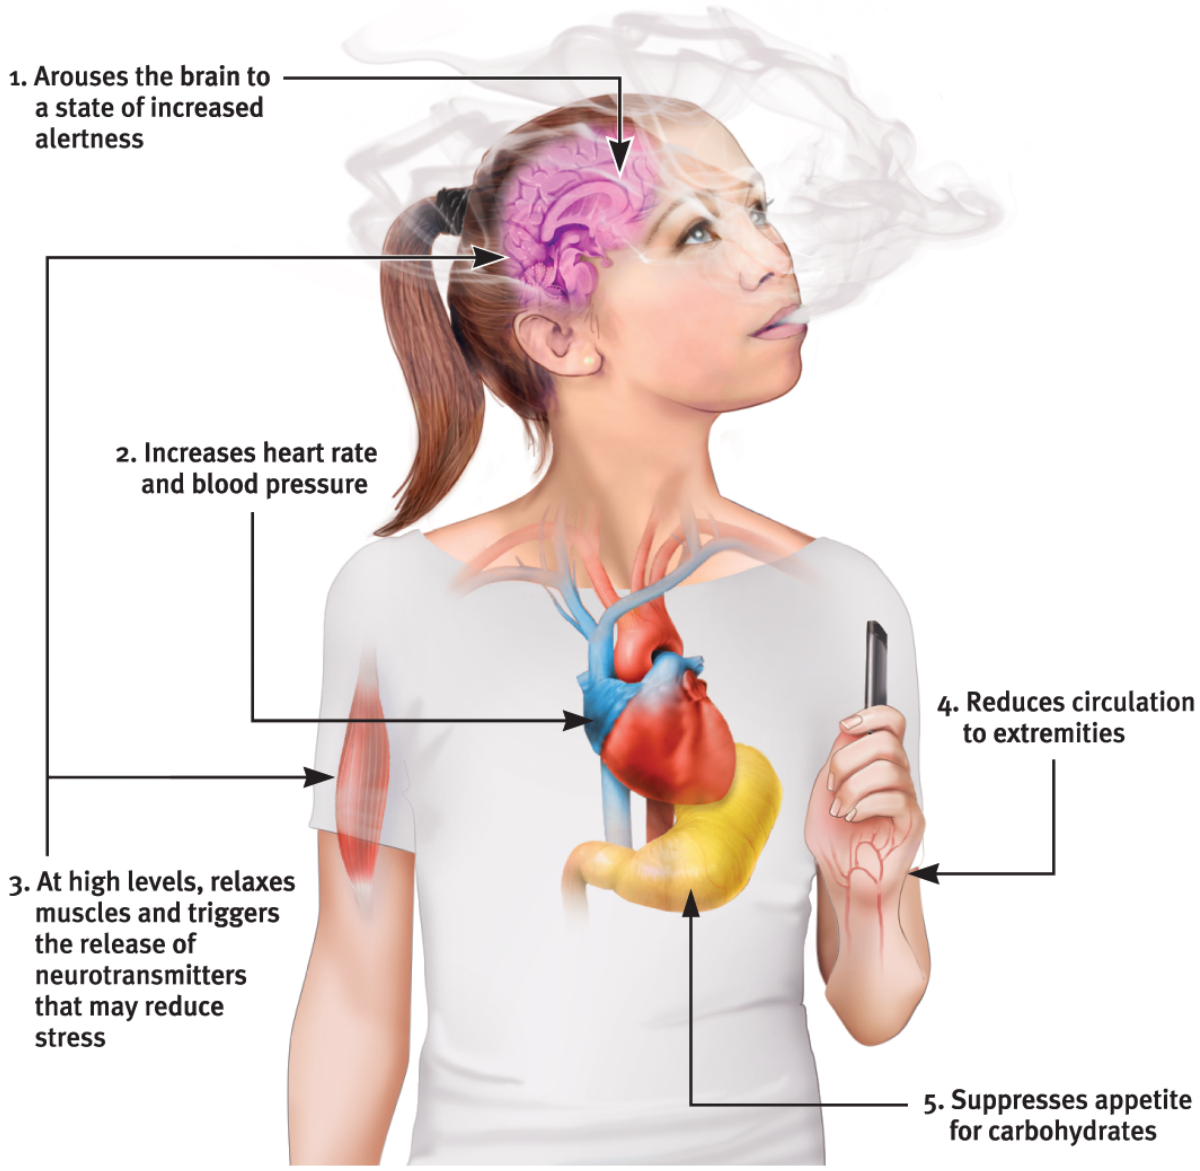
Psychological and drug therapies may be "highly effective" for problematic internet use.[8]

1. Berridge et al., 2009; Robinson & Berridge, 2003. 2. WHO, 2014. 3. Lopez-Quintero et al., 2011. 4. Newport, 2013. 5. Gentile, 2009; Griffiths, 2001; Hoeft et al., 2008. 6. WHO, 2018. 7. Przybylski et al., 2017. 8. Winkler et al., 2013.

Text on the top reads, **Thinking Critically About: Tolerance and Addiction**. L O Q 3-10 What roles do tolerance and addiction play in substance use disorders, and how has the concept of addiction changed?

The three sections are as follows:

The top section labeled, **Tolerance**, shows the following text on the left: With continued use of alcohol and some other drugs, users develop **tolerance** as their brain chemistry adapts to offset the drug effect (*neuroadaptation*). To experience the same effect, users require larger and larger doses, which increase the risk of becoming **addicted** and developing a *substance use disorder*. On the right, two illustrations are depicted on either side of a graph. The vertical axis of the graph represents drug effect increasing from Little effect at the bottom to Big effect at the top. The horizontal axis represents drug dose increasing from small on the left to large on the right. A curved line representing response to first exposure starts from small dose and little effect and gradually increases to big effect as dose increases. A curved line labeled, after repeated exposure, more drug is needed to produce same effect, starts from more drug dose and little effect and gradually rises to large dose with big effect. The illustration on the left of the graph shows an intoxicated man balancing himself on a bar stool, and a text reads, **Drinks rarely**. The illustration on the right of the graph shows a man casually walking with steady feet with many bottles lying at his feet, and a text reads, **Drinks frequently**.



The middle section labeled, **Addiction**, shows the following text on the left: Caused by ever-increasing doses of most psychoactive drugs (including prescription painkillers). Prompts user to crave the drug, to continue use despite adverse consequences, and to struggle when attempting to **withdraw** from it. These behaviors suggest a substance use disorder. Once in the grip of addiction, people want the drug more than they *like* the drug (Berridge, et al., 2009; Robinson and Berridge, 2003). In the middle of the section, a globe is depicted with a wedge labeled 4 percent and a callout reads, 4 percent of the world's people have an alcohol use disorder (W H O, 2014 b). A horizontal bar graph shows the lifetime odds of getting hooked after using various drugs: marijuana, 9 percent; cocaine, 21 percent; alcohol, 23 percent; and tobacco, 68 percent. Source: National Epidemiologic Survey on Alcohol and Related Conditions (Lopez-Quintero et al., 2011). A text on the right of the section reads, Therapy or group support, such as from Alcoholics Anonymous, may help. It also helps to believe that addictions are controllable and that people can change. Many people do voluntarily stop using addictive drugs, without any treatment. "Most people who successfully quit smoking kicked the habit on their own." (Newport, 2013 b). An illustration shows a cigarette tied into a knot.

The bottom section labeled, **Behavior Addictions**, shows the following text on the left: Psychologists try to avoid using "addiction" to label driven, excessive behaviors such as eating, work, sex, and accumulating wealth. An illustration shows a person with a round face eating a tall stack of cheeseburgers, and a speech bubble reads,

I’m ADDICTED to cheeseburgers. The middle of the section shows a person behind a textbox. The text reads, Yet some behaviors can become compulsive and dysfunctional—similar to problematic alcohol and drug use (Gentile, 2009; Grifths, 2001; Hoeft et al., 2008). Behavior addictions include *gambling disorder*. *Internet gaming disorder* is also now a diagnosable condition. (W H O, 2018 b). Such gamers display a consistent inability to resist logging on and staying on, even when this excessive use impairs their work and relationships. One international study of 19,000 gamers found that 1 in 3 had at least one symptom of the disorder. But fewer than 1 percent met criteria for a diagnosis. (Przbylski et al., 2017). A text on the right of the section reads, Psychological and drug therapies may be “highly effective” for problematic internet use (Winkler et al, 2013). An illustration shows a tablet and a capsule.

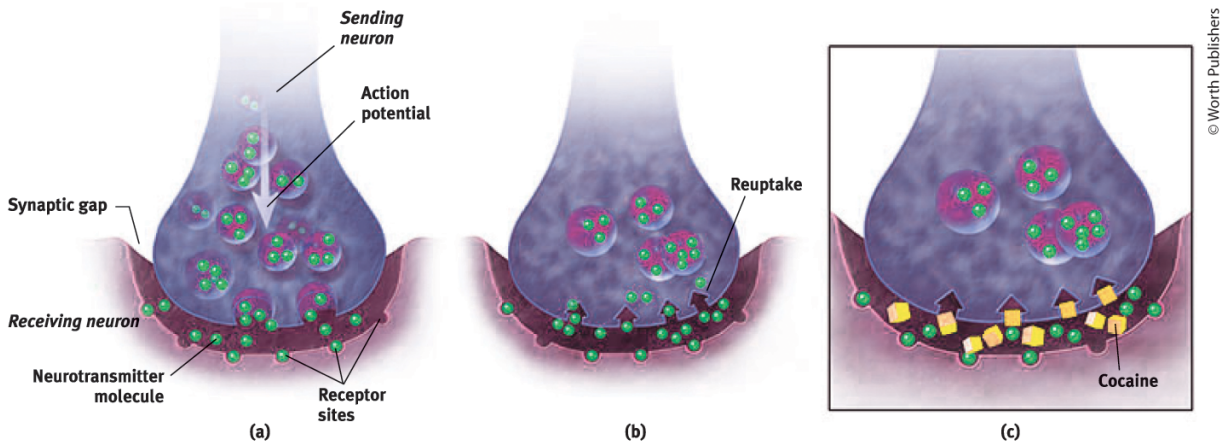
Extended description for FIGURE 10.2 Physiological effects of nicotine



© Worth Publishers

The illustration shows a young woman exhaling smoke from her mouth. Different body organs are highlighted. The effects of

nicotine are listed as follows: 1. Arouses the brain to a state of increased alertness (an arrow points to her brain); 2. Increases heart rate and blood pressure (an arrow points to her heart as well as the major veins and arteries leading from and to her heart); 3. At high levels, relaxes muscles and triggers the release of neurotransmitters that may reduce stress (an arrow points to the bicep in her arm); 4. Reduces circulation to extremities (an arrow points to her wrist, and small blood vessels can be seen from the wrist to her hand); 5. Suppresses appetite for carbohydrates (an arrow points to her stomach).

Return to FIGURE 10.2 Physiological effects of nicotine

Extended description for FIGURE 10.3 Cocaine euphoria and crash

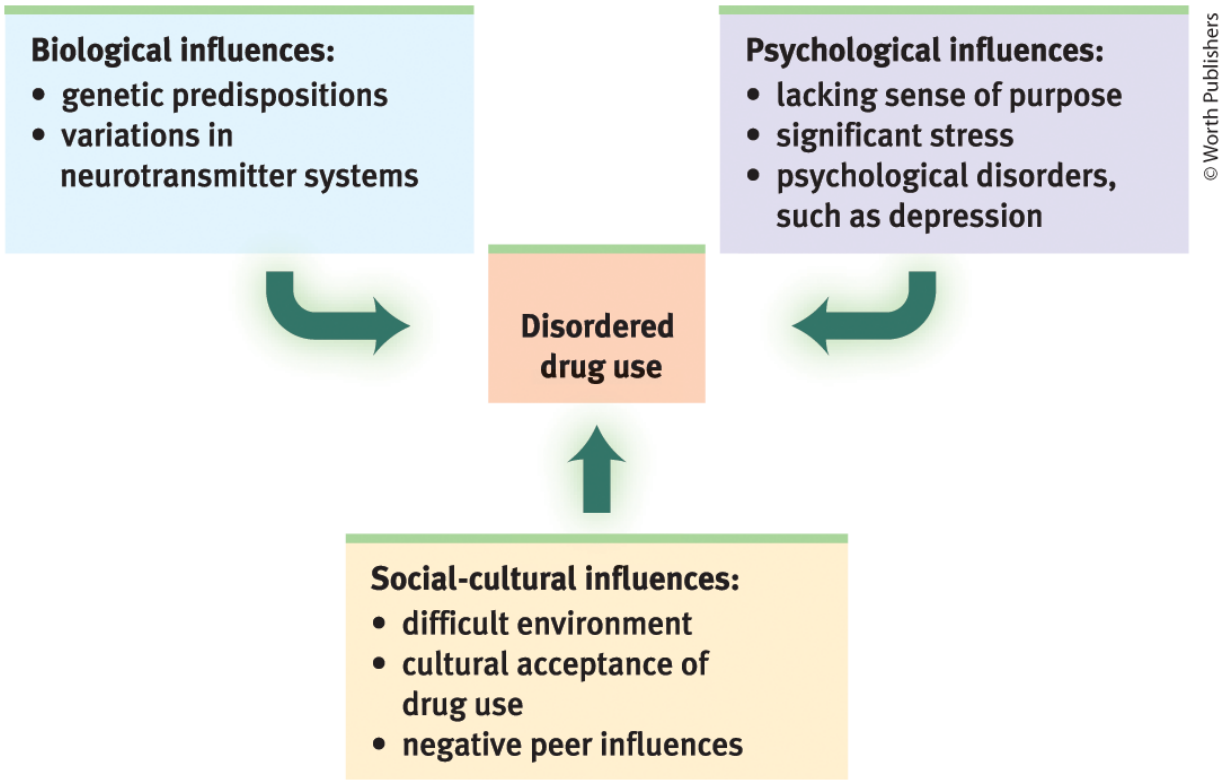
© Worth Publishers

Neurotransmitters carry a message from a sending neuron across a synapse to receptor sites on a receiving neuron.

The sending neuron normally reabsorbs excess neurotransmitter molecules, a process called *reuptake*.

By binding to the sites that normally reabsorb neurotransmitter molecules, cocaine blocks reuptake of dopamine, norepinephrine, and serotonin (Ray & Ksir, 1990). The extra neurotransmitter molecules therefore remain in the synapse, intensifying their normal mood-altering effects and producing a euphoric rush. When the cocaine level drops, the absence of these neurotransmitters produces a crash.

(a) Neurotransmitters carry a message from a sending neuron across a synapse to receptor sites on a receiving neuron. The illustration shows the intersection between the axon terminal of a sending neuron and the dendrite of a receiving neuron. Neurotransmitter molecules are visible in the synaptic gap and are received by receptor sites on the receiving neuron's dendrite surface.



(b) The sending neuron normally reabsorbs excess neurotransmitter molecules, a process called *reuptake*. The illustration shows

neurotransmitters in the synaptic gap being absorbed back up into the axon terminal of the sending neuron and labeled reuptake.

(c) By binding to the sites that normally reabsorb neurotransmitter molecules, cocaine blocks reuptake of dopamine, norepinephrine, and serotonin (Ray and Ksir, 19 90). The extra neurotransmitter molecules, therefore, remain in the synapse, intensifying their normal mood-altering effects and producing a euphoric rush. When the cocaine level drops, the absence of these neurotransmitters produces a crash. The illustration shows cocaine molecules, depicted as yellow cubes, blocking the axon terminal from taking the neurotransmitters back up. The neurotransmitters remain in the synaptic gap and are therefore more likely to fill receptor sites on the receiving neuron's dendrite surface.

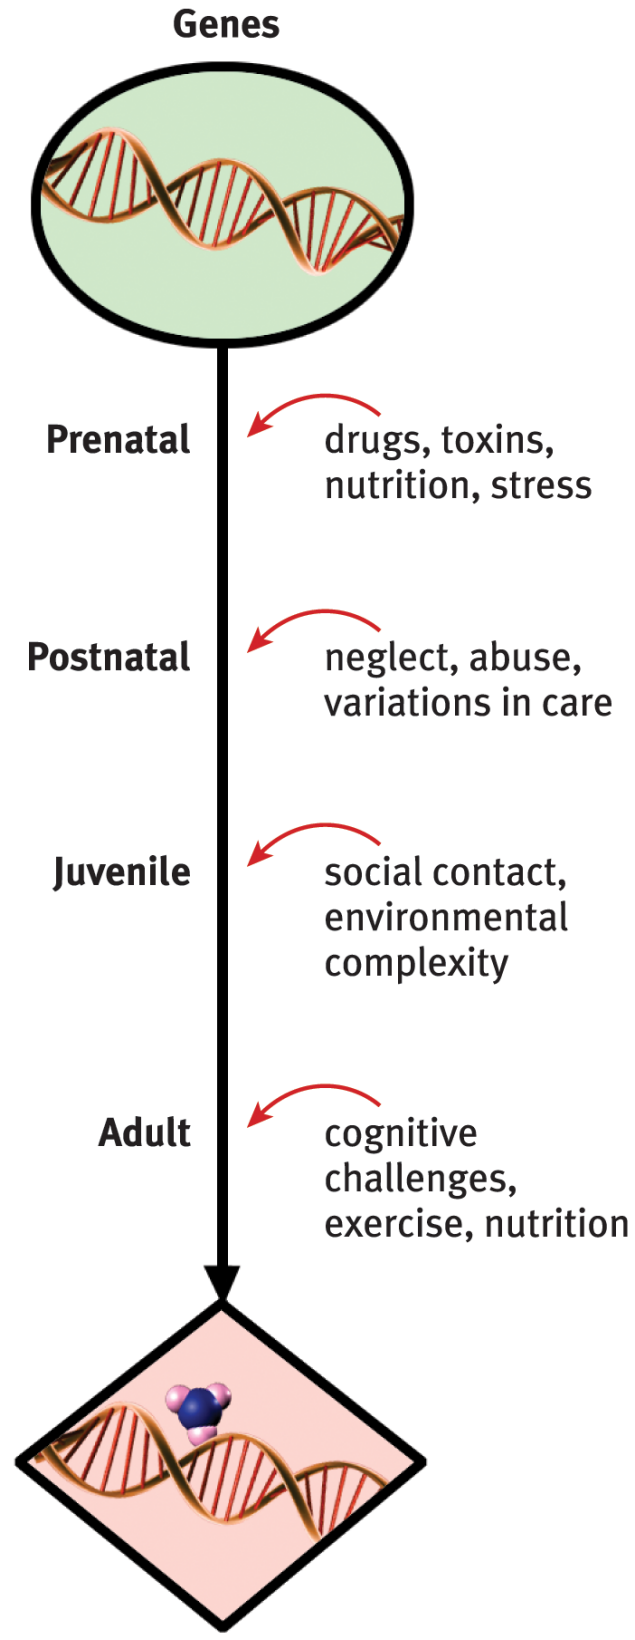
eggs, different genes



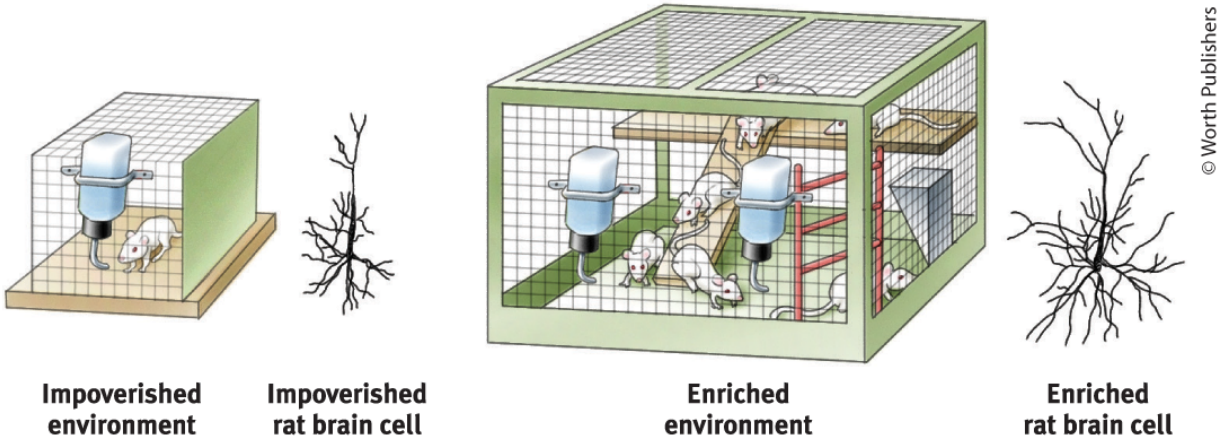
Identical twins
Fraternal twins
Same sex only
Same or different sex
© Worth Publishers

The left side is labeled Identical twins. A sperm cell is depicted fertilizing a single ovum. From there an arrow points to two different zygotes that formed from the single fertilized ovum. Another arrow points to two fetuses in a womb, and it is labeled same sex only. The right side is labeled fraternal twins and shows two sperm cells fertilizing two different ova. An arrow points to two fetuses in a womb, and it is labeled same or different sex.

Return to FIGURE 11.2 Same fertilized egg, same genes; different eggs, different genes

Extended description for FIGURE 11.3

Epigenetic expression



© Worth Publishers

The illustration shows an oval surrounding a double-helix strand of D N A and labeled genes. Below, an arrow points to a diamond with the same D N A strand and the addition of an epigenetic molecule. It is labeled gene expression affected by epigenetic molecules. To the left of the arrow are several life periods, and to the right are examples of influences during these periods, as follows from top to bottom: Prenatal: drugs, toxins, nutrition, stress; Postnatal: neglect, abuse, variations in care; Juvenile: social contact, environmental complexity; and Adult: cognitive challenges, exercise, nutrition.

Return to FIGURE 11.3 Epigenetic expression

Extended description for FIGURE 13.1 Experience affects brain development

© Worth Publishers

The illustration shows two scenes of living situations for rats along with corresponding diagrams of their brain cells. The first scene shows a rat inside a cage in an impoverished environment. In the cage is a water bottle for drinking. A corresponding diagram shows an impoverished rat brain cell. It is thin with fewer branches extending from it and less detailed. The second scene shows a few rats in an enriched environment with a climbing ramp and ladder, two water bottles, and other playthings. A corresponding diagram shows an enriched rat brain cell. This cell has far more detail and proliferation, and more branches from the main cell.

"Remember—we want her to stand out and fit in."

The line graph plots years with values ranging from 18 70 to 20 20, in increments of 50 on the horizontal axis. The vertical axis represents percentage with one of 10 most common names with values ranging from 0 to 40 percent, in increments of 5. The curve representing newborn boys begins at (18 85, 38), gradually decreases to (19 18, 29), gradually increases to (19 47, 34), and finally reaches to end at (2015, 8). The curve representing newborn girls begins at (18 85, 21), reduces to (18 95, 19), gradually increases to (19 47, 23.5), gradually decreases to (19 69, 15), increases to (19 90, 17), and finally reaches to end at (2015, 8). All data are approximate.

The cartoon shows a man sitting and reading a book titled Baby names for tomorrow today. A pregnant woman is sitting beside him with a pen and a notepad. The woman tells the man, “Remember – we want her to stand out and fit in.”

Return to FIGURE 13.3 A child like no other

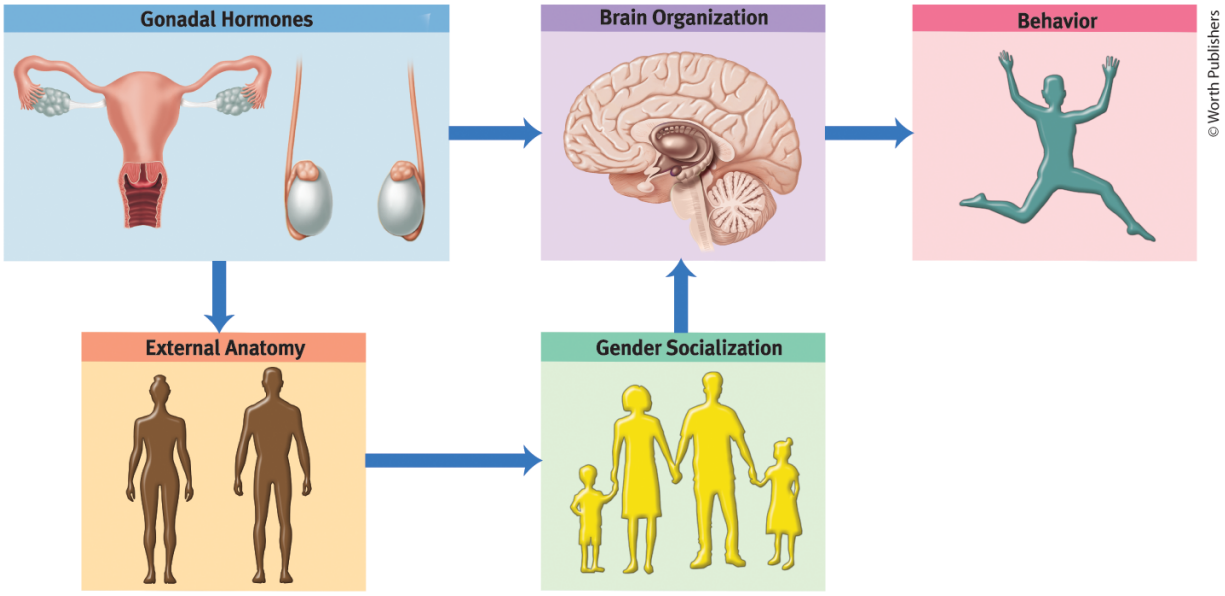
Extended description for Gender bias in the workplace

© Worth Publishers

The first panel is titled, **Differences in PERCEPTION**. An illustration shows a woman standing behind a podium addressing a group of people holding cameras, notepads, and microphones. The audience members are all giving her a skeptical look. A thought bubble above their heads reads, “She’s so aggressive!” On the right is another illustration of a man standing behind a podium addressing a group of people holding cameras, notepads, and microphones. The audience members are all smiling at him. A text bubble above their heads reads, “He’s so take-charge!” The text accompanying the illustrations reads, “Among politicians who seem power-hungry, women are less successful than men (Okimoto and Brescoll, 2010).” To the right, the text reads, “Most political leaders are men.” Under this is a circular graph depicting the globe with text in the middle that reads, “Political leaders.” The graph shows that 74 percent of the circle represents men, who held 74 percent of seats in the world’s governing parliaments in 2022 (I P U, 20 22). It also shows that the remaining 26 percent represents women political leaders. The text reads, “People around the world tend to see men as more powerful (Eagly et al., 20 20).” The text below reads, “When groups form, whether as juries or companies, leadership tends to go to males (Colarelli et al., 2006). In a study of 2000 plus U.S. companies, male C E Os outnumbered female C E Os 17 to 1 (Kapadia, 20 21).”

The second panel is titled, **Differences in COMPENSATION**. Women in traditionally male occupations have received less than their male colleagues (L M I C, 20 20). Text below in the left half of the panel reads, “**Medicine**. Over their careers, how much more male doctors

will earn than female doctors (Whaley et al., 20 21)," with an illustration showing 2,000,000 dollars above a line and a large dollar sign below it. On the right side of the panel, text reads, "**Academia. Female** research grant applicants have received lower quality of researcher ratings and have been less likely to be funded. (Witteman et al., 2019) (But as we will see, gender attitudes and roles are changing)." Beside this text is the female symbol inside a downward-facing arrow.

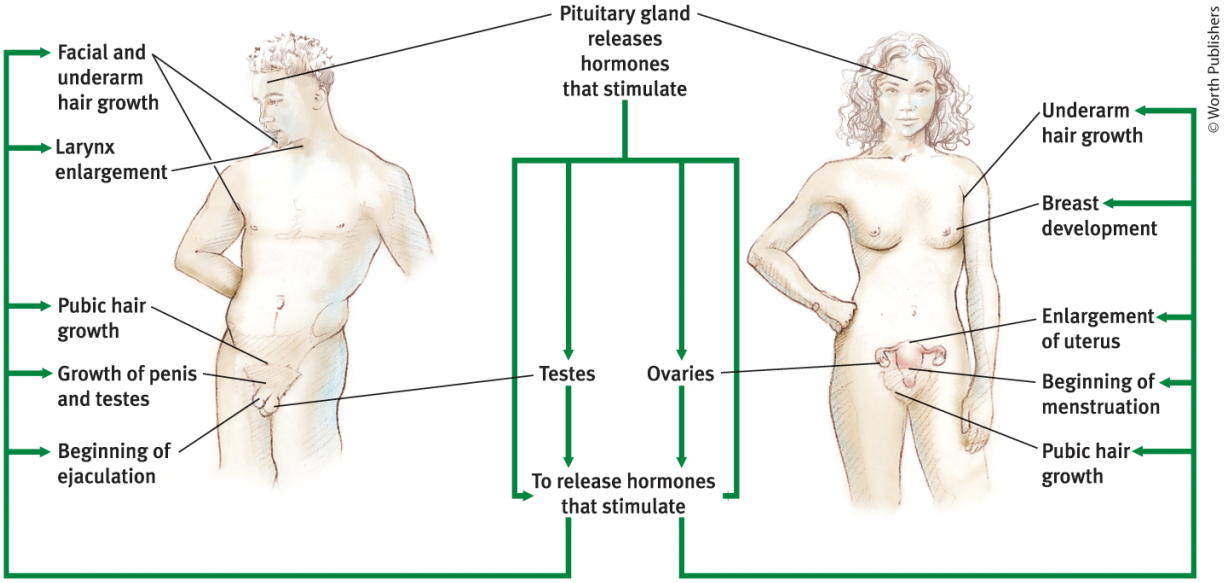


The third panel is titled, **Differences in FAMILY-CARE RESPONSIBILITY**. The illustration shows a woman entangled in the wires of a laptop and phone, seated at a desk strewn with papers. One arm is holding a baby and on the other arm is a handbag. She is checking her watch. Text reads, "**U.S. mothers** still do nearly **twice** as much child care as **fathers** (C E A, 2014; Parker and Wang, 2013; Pew, 2015). In the workplace, women are less often driven by money and status, compromise more, and more often opt for reduced work hours (Nikolova and Lamberton, 2016; Pinker, 2008)."

The fourth panel is titled, **What else contributes to WORKPLACE GENDER BIAS?** The first box in this panel has a heading that reads, "**Social norms**." Under the heading, the text reads, "In most societies, men place more importance on power and achievement, and are socially dominant (Gino et al., 2015; Schwartz and Rubel-Lifschitz, 2009)." The second box in this panel has a heading that reads, "**Leadership styles**." Under this heading, the text reads, "**Men** are more *directive*, telling people what to do and how to do it." An

illustration shows a man in a suit instructing an employee. "**Women** are more *democratic*, welcoming others' input in decision making (Eagly and Carli, 2007; van Engen and Willemsen, 2004)." An illustration shows a woman in a suit smiling, listening to an employee. The third box in this panel has a heading that reads, "**Interaction styles**." Text under the heading reads, "**Women** are more likely to express support (Aries, 19 87; Wood, 19 87). **Men** are more likely to offer opinions (Aries, 19 87; Wood, 19 87)." The illustration shows a smiling woman taking notes while listening to a man. The fourth box in this panel has a heading that reads, "**Everyday behavior**." Text under the heading reads, "**Women** smile and apologize more than men (Leaper and Ayres , 2007; Major et al., 19 90; Schumann and Ross, 2010). **Men** are more likely to talk assertively, interrupt, initiate touches, and stare (Leaper and Ayres, 2007; Major et al., 19 90; Schumann and Ross, 2010)." An illustration shows a woman in a suit and folded hands listening to a man. Another illustration shows a man in a suit with his hand on another man's shoulder. The fifth box in this panel has a heading that reads, "**Yet GENDER ROLES VARY WIDELY across place and time**." Text under the heading reads, "Women are increasingly represented in leadership (now 50 percent of Canada's cabinet ministers) and in the workforce. In 19 63, the Harvard Business School admitted its first women students. Among its Class of 20 20, 41 percent were women (Harvard Business School, 2019). In 19 60, women were 6 percent of U.S. medical students. Today, they are slightly more than half (A A M C, 2018)."

Return to Gender bias in the workplace



Extended description for FIGURE 13.4 From hormones to behavior

The illustration shows five boxes. The first box has male and female reproductive systems labeled gonadal hormones with one right arrow and one down arrow. The down arrow points to a box that has images of a man and a woman labeled external anatomy, and the right arrow points to a box that has a lateral view of the brain labeled brain organization. A right arrow from external anatomy points to a box that has an icon of a family of four members labeled gender socialization that has an up arrow pointing to the brain organization. A right arrow from brain organization points to a box that has an icon of a person jumping labeled behavior.

Return to FIGURE 13.4 From hormones to behavior

Extended description for FIGURE 13.5 Body changes at puberty

Two figures highlight male and female anatomy, with labels for the organs and lines to show the hormonal relationships. Text pointing to pituitary glands in both foreheads reads, Pituitary gland releases hormones that stimulate the ovaries in females and the testes in males. For females, they further release hormones that stimulate underarm hair growth, breast development, enlargement of the uterus, beginning of menstruation, and pubic hair growth. For males, the glands release hormones that stimulate facial and underarm hair growth, larynx enlargement, pubic hair growth, growth of penis and testes, and beginning of ejaculation.

Return to FIGURE 13.5 Body changes at puberty

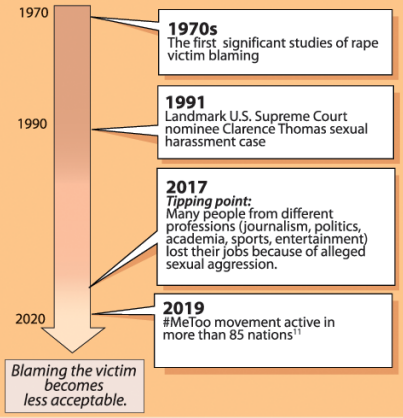
Extended description for Sexual

aggression

Thinking Critically About:
Sexual Aggression

Definition of Sexual Aggression

Sexual harassment involves making unwanted sexual advances, obscene remarks, or requests for sexual favors.[1]



Sexual assault is "any type of sexual contact or behavior that occurs without the explicit consent of the recipient," such as unwanted touching, molestation, and attempted or completed rape.[2]

Cultural Effects on Our Views

By Place:
Some cultures view victims of sexual aggression as guilty of disgracing their families. In India and Pakistan, male family members kill an unknown number of women—one source estimates 1000 annually in each country[10]—for dishonoring their families.

Over Time:
Changes in global norms have made it less acceptable to blame victims of sexual aggression.

Victims

In the U.S., **81%** of women and **43%** of men report having experienced sexual aggression in their lifetime.[3]

Sexual aggression affects people of *all ethnic groups*.[4]

Nearly **70%** of rape victims are between the ages of 11 and 24.4.[4]

In a National School Climate survey, **8** out of **10** gay or lesbian adolescents reported experiencing sex-related harassment in the prior year.[5]

Effects on Well-Being

Thanks to human resilience, victims of sexual aggression often recover and lead healthy and meaningful lives. Yet many also suffer serious setbacks, including:

- Greater anxiety, depression, and risk for posttraumatic stress disorder[6]
- Disrupted sleep[7]
- Poor physical health[8]
- Difficulty trusting new relationship partners[9]

How to Reduce Sexual Aggression

Therapy to treat sexual aggressors has not been very effective.[12] However, other, broader-based strategies do work:

Encourage victims to report their experiences to authority figures (parents, supervisors, law enforcement officials) and to share their experiences publicly.[13]

Empower victims to take control of their situation and refuse to let their perpetrators dominate or manipulate them. Adjust social norms so that victims feel safe reporting their experiences.

Educate people about preventive bystander intervention strategies, such as "Green Dot," which has reduced sexual aggression in communities by as much as 20%.[14]

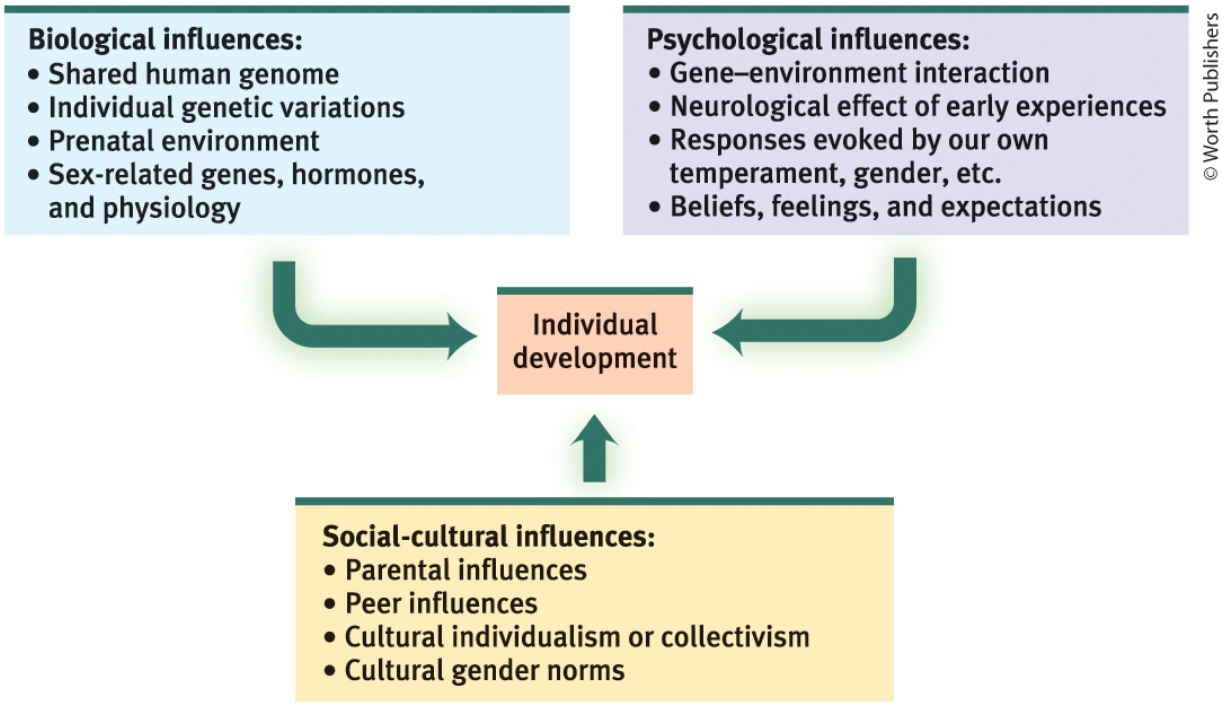
© Worth Publishers

A heading in the top right reads, **Definition of Sexual Aggression.** Under this heading are two boxes side by side. The box on the left has the text, **Sexual harassment** involves making unwanted sexual advances, obscene remarks, or requests for sexual favors (McDonald, 2012; U S E E O C, 2018). Under the text is an illustration showing two young men hooting at and ogling two young women, who clearly look uncomfortable. The box on the right has the text, **Sexual assault** is any type of sexual contact or behavior that occurs without the explicit consent of the recipient," such as unwanted touching, molestation, and attempted or completed rape (U S D O J, 2018). The illustration shows a man touching a girl's leg against her will as they sit at a work table.

In the lower left quadrant are two boxes. At the top is a box entitled, **Victims**. The text reads, In the U.S., **81 percent** of women and **43 percent** of men report having experienced sexual aggression in their lifetime (Stop Street Harassment, 2018). Sexual aggression affects people of *all ethnic groups* (Black et al., 2011). Nearly **70 percent** of rape victims are between the ages of 11 and 24.4 (Black et al., 2011). In a National School Climate survey, **8** out of **10** gay or lesbian adolescents reported experiencing sex-related harassment in the prior year (G L S E N, 2012).

The lower box is titled, **Effects on Well-Being**. The text reads, Thanks to human resilience, victims of sexual aggression often recover and lead healthy and meaningful lives. Yet many also suffer serious setbacks, including: bullet 1, Greater anxiety and

depression, and risk for posttraumatic stress disorder (Choudhary et al., 2012; Krahé and Berger, 2017; Snipes et al., 2017; Zanarini et al., 19 97); bullet 2, Disrupted sleep (Krakow et al., 2001, 2002); bullet 3, Poor physical health (Schuyler et al., 2017; Zinzow et al., 2011); and bullet 4, difficulty trusting new relationship partners (Muldoon et al., 2016; Starzynski et al., 2017). An illustration shows a young woman's face showing severe emotional distress.



The heading in the upper right quadrant reads **Cultural Effects on Our Views**. There are two boxes side-by-side under this column heading. The box on the left has the text, **By Place:** Some cultures view victims of sexual aggression as guilty of disgracing their families. In India or Pakistan, male family members kill an unknown number of women—one source estimates 1000 annually in each country (H B V A, 2018)—for dishonoring their families. The box on the right has the text, **Over Time**: Changes in global norms have made it less acceptable to blame victims of sexual aggression. Below the text is an illustration of a large downward-facing arrow with the label 19 70 at the top, the label 19 90 near the middle, and the label 20 20 at the bottom near the arrow point. Directly under the arrow is the text, *Blaming the victim becomes less acceptable*. A textbox pointing to the 19 70 label reads, **19 70s**: The first significant studies of rape victim blaming. Another box points below the 19 90 label, with the text, **19 91**: Landmark U.S. Supreme court nominee Clarence Thomas sexual harassment case. A third box points above the 20 20 label and reads, **2017**: Tipping point: Many people from different professions (Journalism, politics, academia, sports,

entertainment) lost their jobs because of alleged sexual aggression. A fourth textbox points to the 20 20 label and reads, **2019:** hashtag MeToo movement active in more than 85 nations (Stone and Vogelstein, 2019).

The box in the lower right quadrant is titled, **How to Reduce Sexual Aggression**. The text reads, Therapy to treat sexual aggressors has not been very effective (Grønnerød et al., 2015; Klapilová et al., 2019). However, other, broader-based strategies do work: **Encourage** victims to report their experiences to authority figures (parents, supervisors, law enforcement officials) and to share their experiences publicly (Holland et al., 2020). **Empower** victims to take control of their situation and refuse to let their perpetrators dominate or manipulate them. Adjust social norms so that victims feel safe reporting their experiences. **Educate** people about preventive bystander intervention strategies, such as "Green Dot," which has reduced sexual aggression in communities by as much as 20 percent (Coker et al., 2017). The first illustration in this panel is a Time Magazine Person of the Year cover showing five women of diverse ethnicities and ages. The cover title reads, The Silence Breakers 2017. The second illustration is the Indianapolis Star newspaper showing the face of a bearded, bespectacled man in a prison jumpsuit. The headline reads, Disgraced Dr. Nassar ellipses sexual abuse ellipses 332 victims (Jesse, 2019).

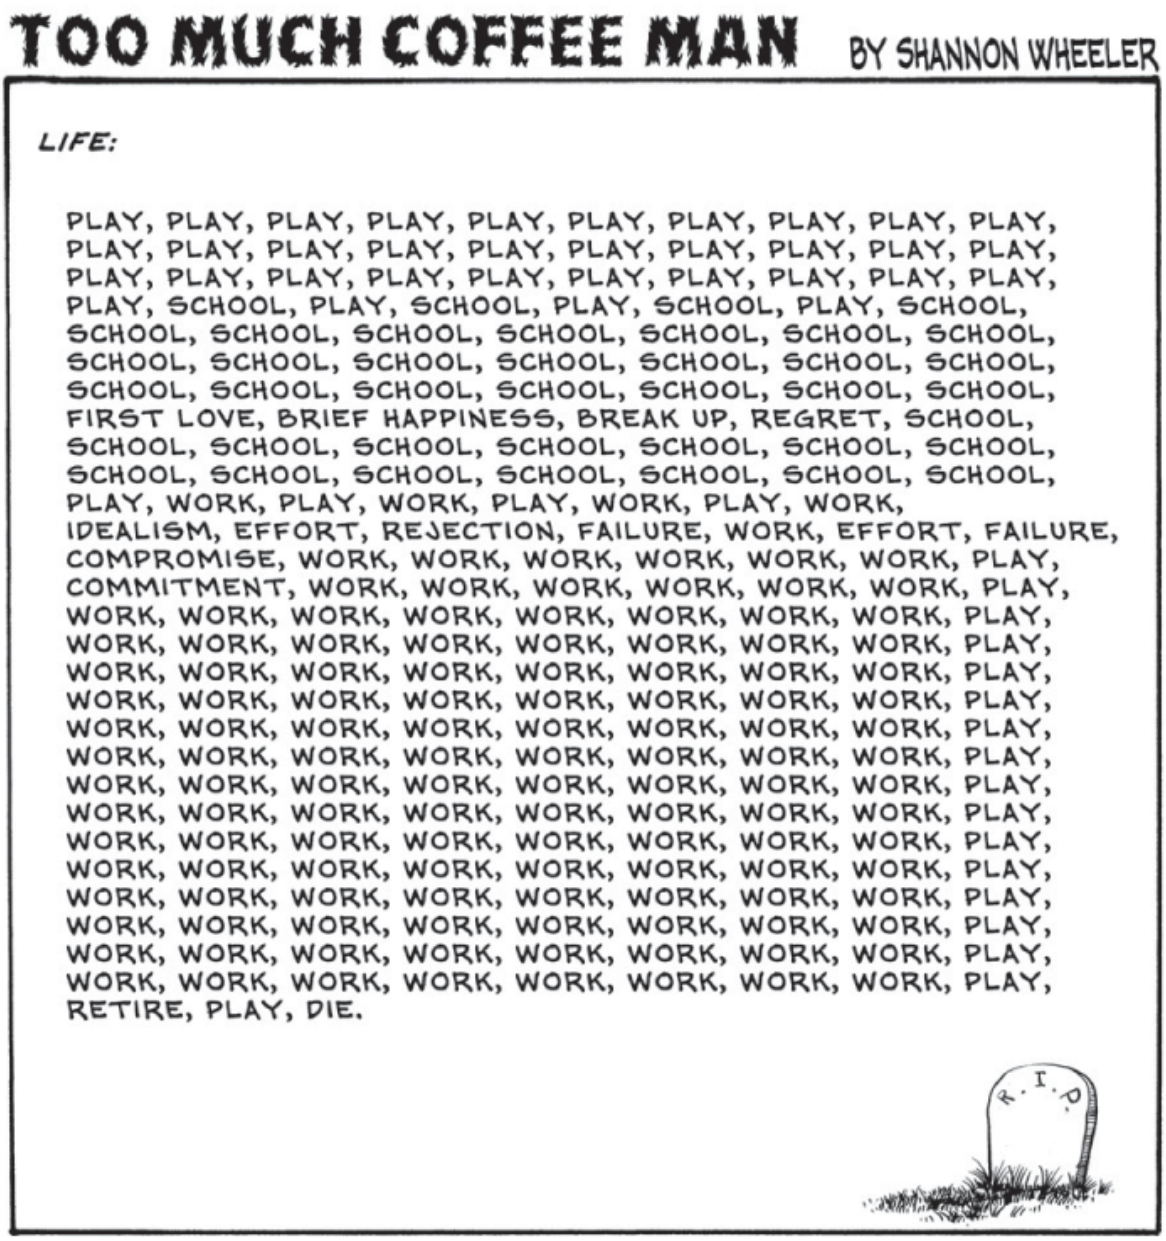
Extended description for FIGURE 13.6 The biopsychosocial approach to development



© Worth Publishers

The illustration has four boxes, two boxes at the top, one box in the middle, and one at the bottom. The top left box reads, **Biological influences**: shared human genome, individual genetic variations, prenatal environment, and sex-related genes, hormones, and physiology. The top right box reads, **Psychological influences**: gene-environment interaction, neurological effect of early experiences, responses evoked by our own temperament, gender, etcetera. and beliefs, feelings and expectations. The bottom box reads, **Social-cultural influences**: parental influences, peer influences, cultural

individualism or collectivism, and cultural gender norms. These three boxes point to a box in the middle that reads, **Individual development.**

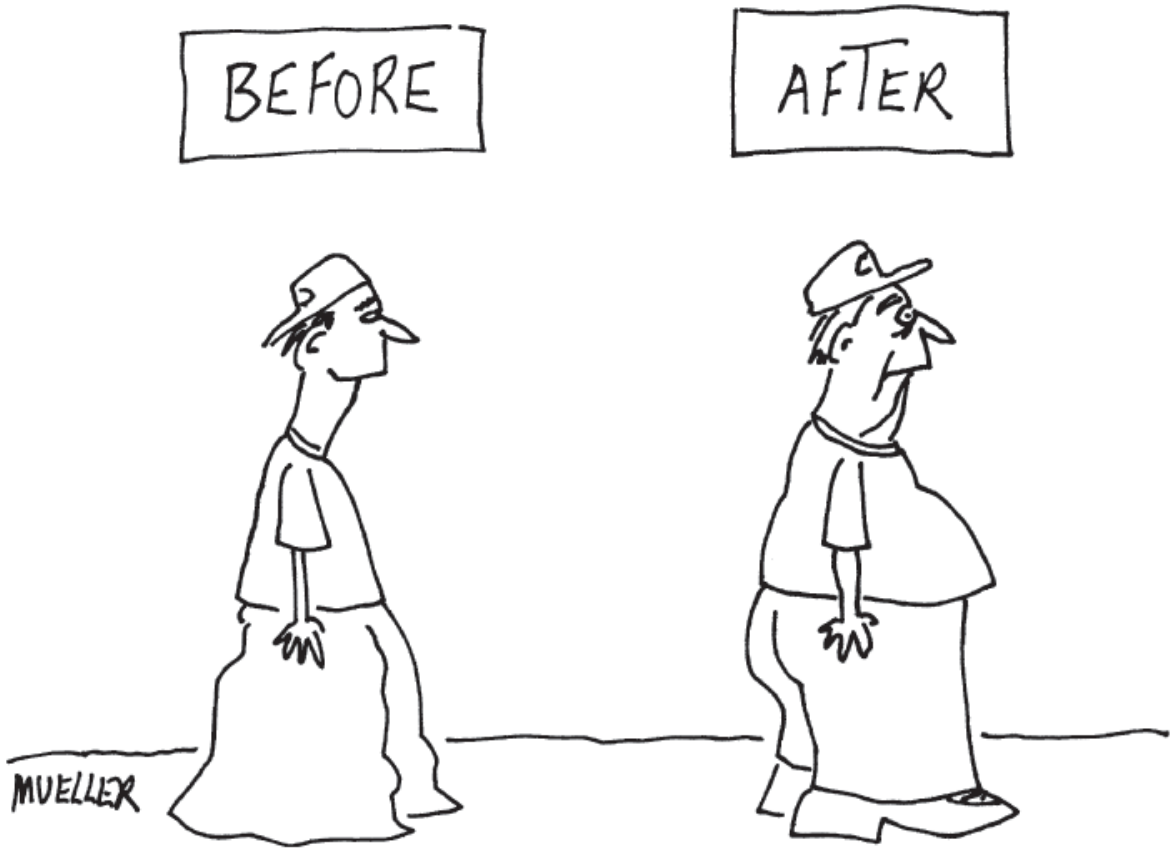
Extended description for FIGURE 14.1 Comparing the stage theories



© Worth Publishers

A horizontal scale beneath the illustration plots age from birth to death with the years from 1 to 14 marked in increments of 1. To the right of 14 years is a foreshortened period that covers the rest of life ending with death. The three theories are represented by three horizontal strips above the axis. The first strip is labeled Lawrence Kohlberg: Moral development and is divided into three sections as follows: Preconventional morality, from birth to about 8 years of age; Conventional morality, from age 8 to age 14; and Postconventional morality for some, from age 14 to the rest of the life through death. The second strip is labeled Erik Erikson: Psychosocial development and is divided into eight sections as follows: Basic trust, from birth to age 1; Autonomy, from age 1 to age 3; Initiative, from age 3 to age 6; Competence, from age 6 to about 12; Identity, from age 12 to past age 14 and into early adulthood;

Intimacy, early adulthood; Generativity, middle adulthood; and Integrity, from late adulthood to death. The third strip is labeled Jean Piaget: Cognitive development and is divided into four sections as follows: Sensorimotor, from birth to about 2 years of age; Preoperational, from age 2 to age 7; Concrete operational, from age 7 to age 11; and Formal operational, from age 11 through the remaining lifespan till death. All data are approximate.

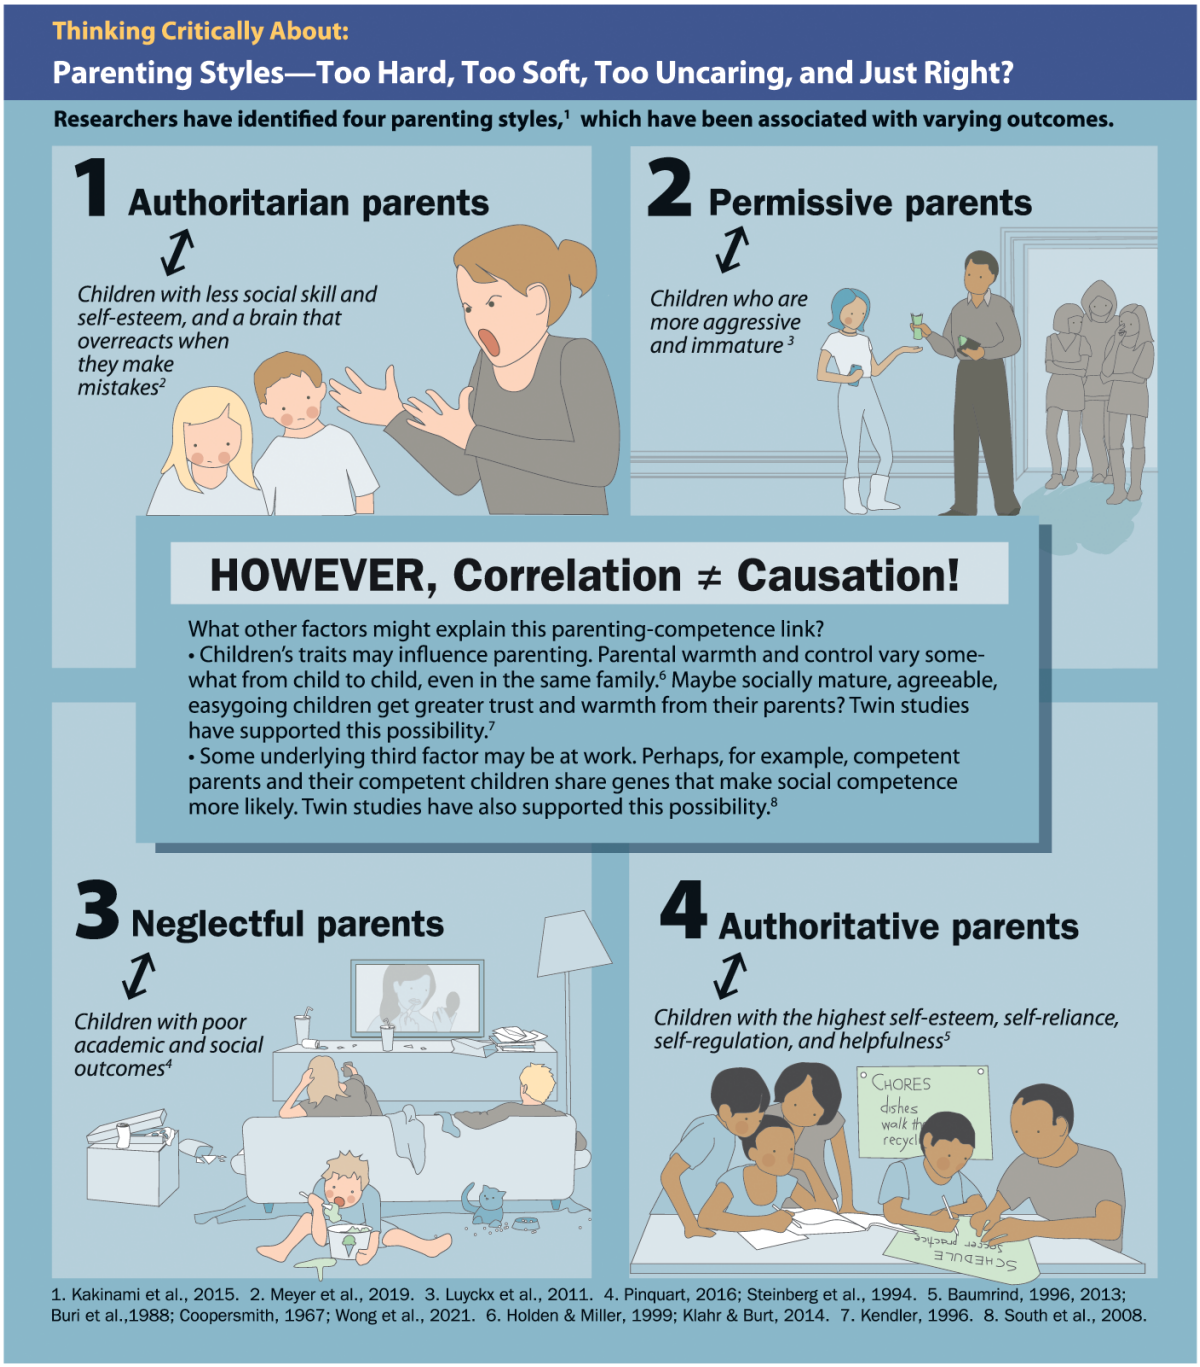
Extended description for FIGURE 15.9 Infants' distress over separation



In the graph, the horizontal axis represents age (months) and ranges from 3 and a half to 29. The vertical axis represents percentage of infants who cried when their mother left and ranges from 0 to 100 percent. A curve labeled day care starts from (3 and a half, 10 percent); passes through (9 and a half, 60 percent), (13 and a half, 85 percent), and (20, 82 percent); and ends at (29, 70 percent). A curve labeled home starts from (3 and a half, 30 percent); passes through

(5 and a half, 6 percent), (9 and a half, 40 percent), (13 and a half, 97 percent), and (20, 95 percent); and ends at (29, 60 percent). All data are approximate.

Return to FIGURE 15.9 Infants' distress over separation

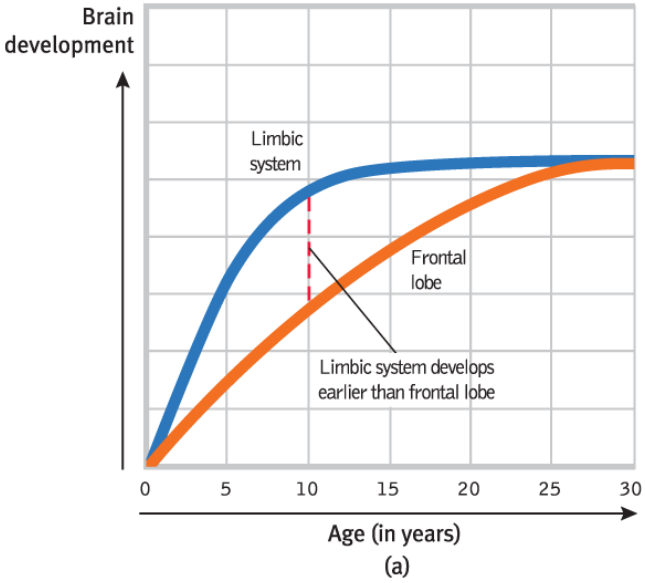
Extended description for Parenting styles

© Worth Publishers

The introductory text reads, Researchers have identified four parenting styles (Kakinami et al., 2015), which have been associated with varying outcomes. The infographic is divided into four sections.

The first section's heading reads, **1. Authoritarian Parents.** A two-way arrow indicating a two-way relationship is underneath this title, leading to the text, *Children with less social skill and self-esteem, and a brain that overreacts when they make mistakes* (Meyer et al., 2019). The illustration shows a mother yelling at her two children.

The second section's heading reads, **2. Permissive Parents.** A two-way arrow indicating a two-way relationship is underneath this title, leading to the text, *Children who are more aggressive and immature* (Luyckx et al., 2011). The illustration shows a father giving money to his daughter from his wallet while her friends are waiting by the door. One of the friends is smoking.



The third section's heading reads, **3. Negligent Parents.** A two-way arrow indicating a two-way relationship is underneath this title, leading to the text, *Children with poor academic and social outcomes* (Pinquart, 2016; Steinberg et al., 19 94). The illustration shows an untidy living room where the mother and the father are watching television on the couch, while their child is sitting on the floor behind the couch, eating ice cream from the tub.

The fourth section's heading reads, **4. Authoritative parents.** A two-way arrow indicating a two-way relationship is underneath this title, leading to the text, *Children with the highest self-esteem, self-reliance, self-regulation, and helpfulness* (Baumrind, 19 96, 2013; Buri et al., 19 88; Coopersmith, 19 67; Wong et al., 2021). The illustration shows a father helping his son create a schedule list, while the mother is helping two other children study. A chart on the wall reads, Chores: dishes, walk the dog, recycle.

The text superimposed in the center over all four illustrations reads, **HOWEVER, Correlation is not equal to Causation!** What other factors might explain this parenting-competence link? A bulleted list begins. Bullet item 1 text reads: Children's traits may influence parenting. Parental warmth and control vary somewhat from child to child, even in the same family. (Holden and Miller, 19 99; Klahr and Burt, 2014). Maybe socially mature, agreeable, and easygoing children evoke greater trust and warmth from their parents? Twin studies have supported this possibility (Kendler, 19 96). Bullet item 2 text reads: Some underlying third factor may be at work. Perhaps, for example, competent parents and their competent children share genes that make social competence more likely. Twin studies have also supported this possibility (South et al., 2008).

The graph plots age in years increasing from left to right on the horizontal axis and ranges from 0 to 30, in increments of 5. The vertical axis represents brain development increasing from bottom to top. The blue line represents the limbic system and the orange line represents the frontal lobe. The data in the graph is as follows: The line for the limbic system starts from (0, 0) gradually reaches (15, six-eighth of the vertical axis), and slightly increases to end beyond six-eighth of the vertical axis by 30 years. The line for the frontal lobe starts from (0, 0) and gradually increases to end beyond six-eighth of the vertical axis by 30 years. There is a dotted line from (10, six-eighth of the vertical axis) of the limbic system line to (10,

two-point eight-eighth of the vertical axis) of the frontal lobe line and the labeled limbic system develops earlier than frontal lobe. The second part shows a photo of a boy pushing two girls seated on a skateboard. All data are approximate.

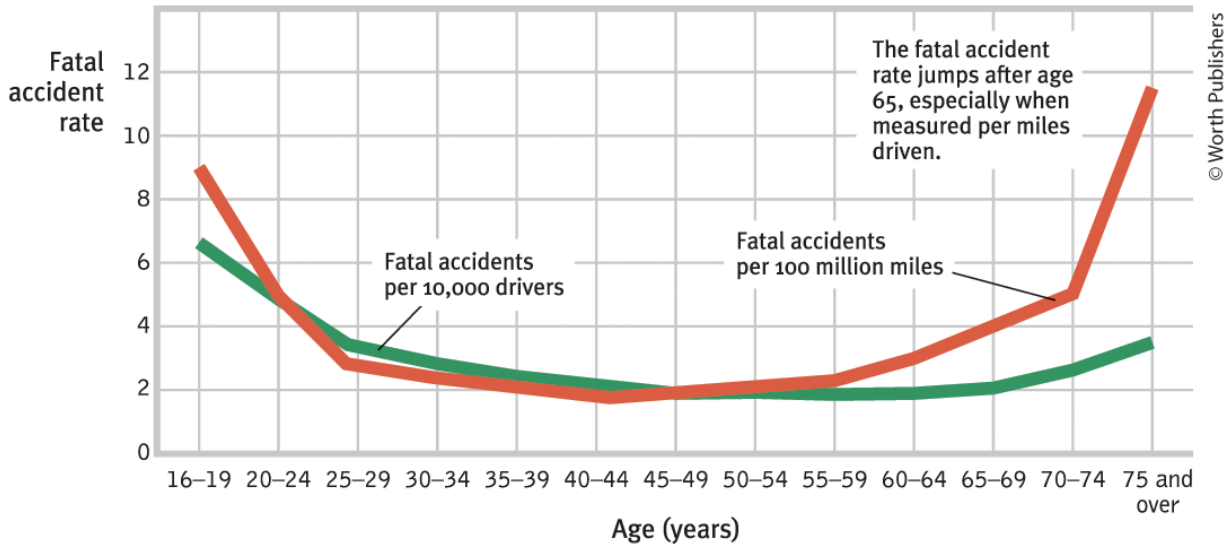
Extended description for FIGURE 17.1 Life expectancy since 17 70, by world regions

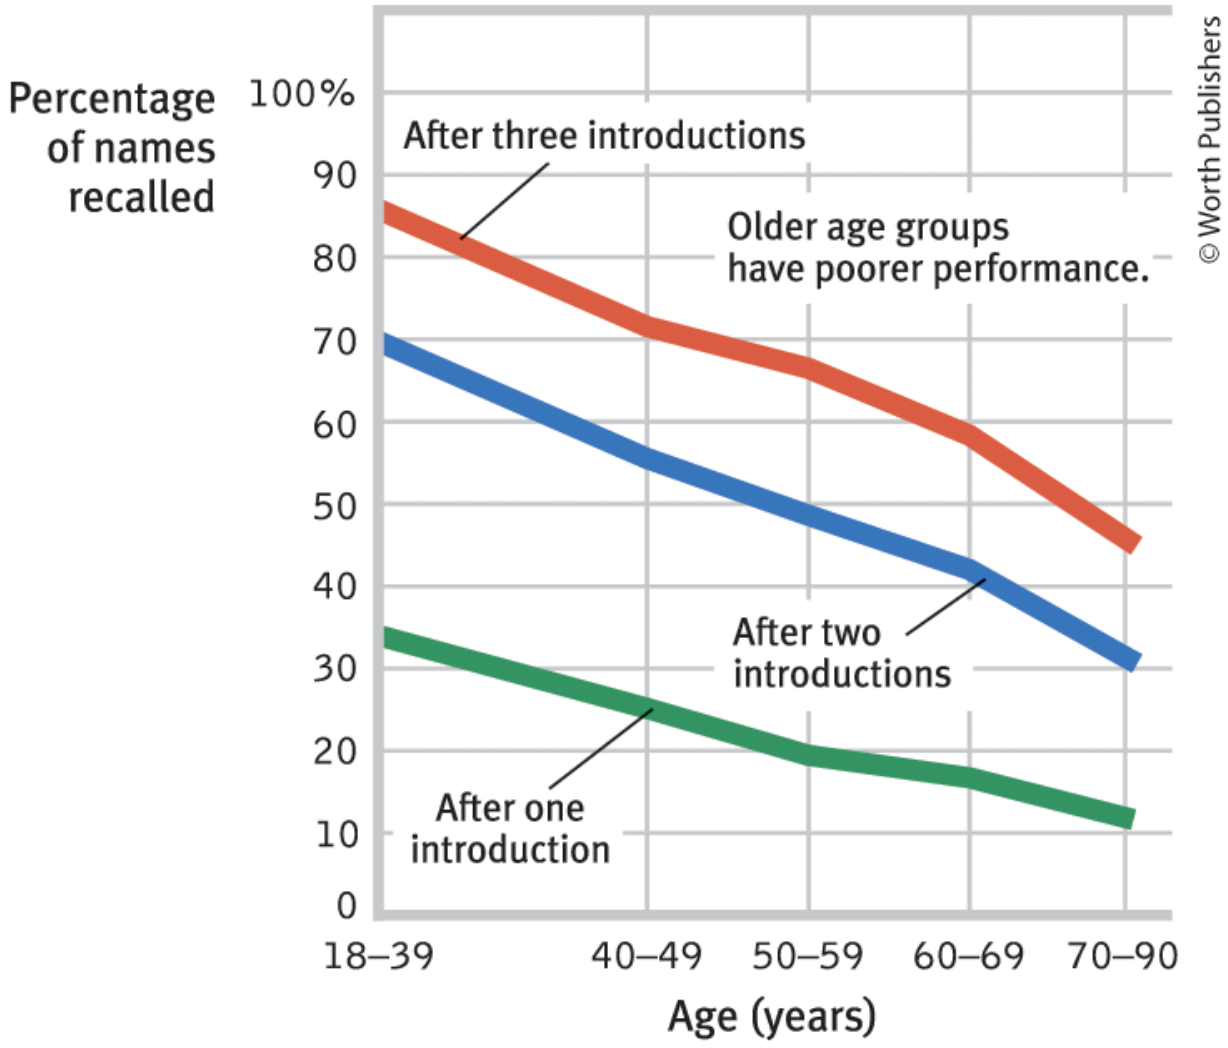


The horizontal axis represents Year and is labeled 17 70, 18 80, 18 50, 1900, 19 50, 2000, and 2019. The vertical axis represents Years of age and ranges from 0 to 90, in increments of 10. The curve for Europe starts at (17 70, 35 years); passes through (18 80, 32 years), (18 50, 38 years), (1900, 42 years), (19 50, 62 years), and (2000, 76 years); and ends at (2019, 79 years). The curve for Oceania starts at (17 70, 37 years); passes through (18 80, 37 years), (18 50, 37 years), (1900, 49 years), (19 50, 59 years), and (2000, 75 years); and ends at (2019, 79 years). The curve for Americas starts at (17 70, 37 years); passes

through (18 80, 37 years), (18 50, 37 years), (1900, 40 years), (19 50, 60 years), and (2000, 75 years); and ends at (2019, 78 years). The curve for Asia starts at (17 70, 29 years); passes through (18 80, 29 years), (18 50, 29 years), (1900, 29 years), (19 50, 42 years), and (2000, 69 years); and ends at (2019, 73 years). The curve for World starts at (17 70, 29 years); passes through (18 80, 29 years), (18 50, 30 years), (1900, 32 years), (19 50, 48 years), and (2000, 68 years); and ends at (2019, 72 years). The curve for Africa starts at (17 70, 28 years); passes through (18 80, 28 years), (18 50, 28 years), (1900, 28 years), (19 50, 38 years), and (2000, 53 years); and ends at (2019, 62 years). All data are approximate.

Return to FIGURE 17.1 Life expectancy since 17 70, by world regions

Extended description for FIGURE 17.2 Age and driver fatalities

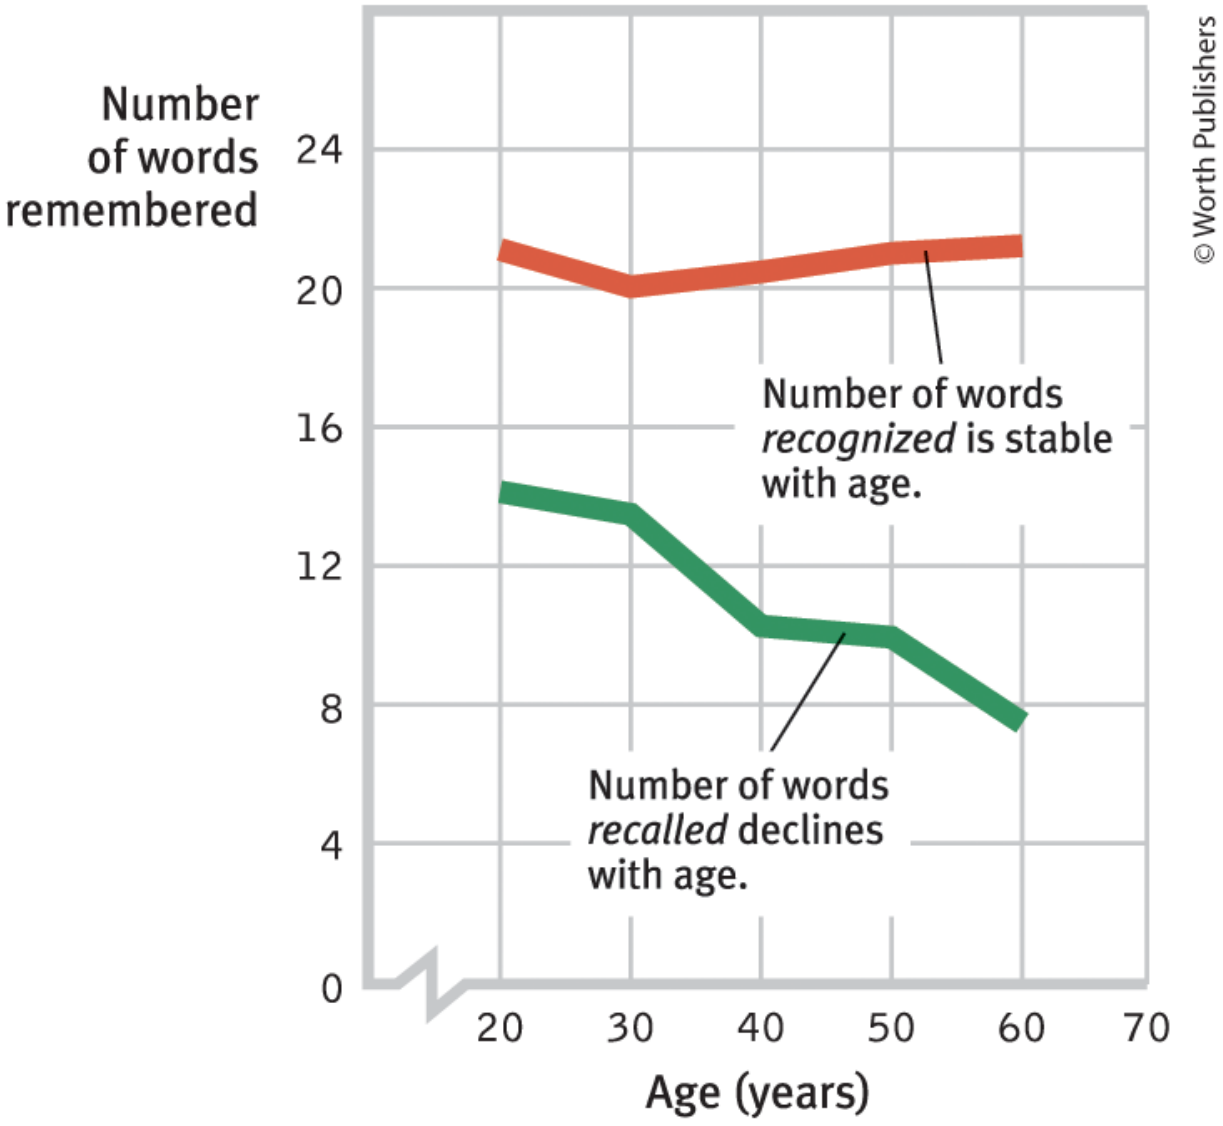


The horizontal axis represents age (years) and ranges from age group 16 to 19 to age 75 and older. The vertical axis represents fatal accident rate and ranges from 0 to 12, in increments of 2. The graph plots two curves for fatal accidents per 10,000 drivers and fatal accidents per 100 million miles. Accidents are approximately 6.5 per 10,000 drivers and 9 per million miles in 16 to 19-year-olds. These numbers decrease steadily until age 25 when both level off and stay at approximately 2 per 10,000 drivers and 2 per 100 million miles from ages 25 to 55. After age 55, fatal accidents per 100 million miles rise sharply. The fatal accident rate jumps after age 65, especially when measured per miles driven. The fatal accidents per 10,000

drivers rate also increase with age, although less dramatically. The curves end at 3.5 for fatal accidents per 10,000 drivers and 11.5 for fatal accidents per 100 million miles at age 75 and older. All data are approximate.

Return to FIGURE 17.2 Age and driver fatalities

Extended description for FIGURE 17.3 Tests of recall

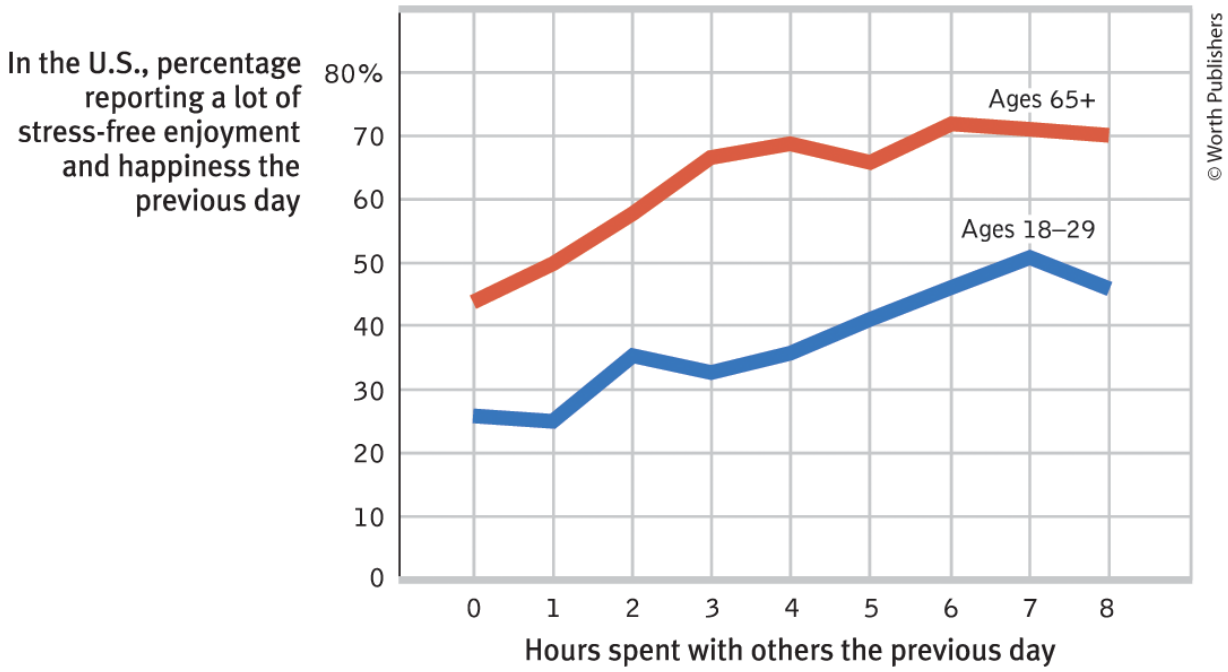


The horizontal axis represents age (years) and is labeled 18 to 39, 40 to 49, 50 to 59, 60 to 69, and 70 to 90. The vertical axis represents percentage of names recalled and ranges from 0 to 100 percent, in increments of 10. The curve labeled After three introductions starts

from (18 to 39 years, 85 percent); passes through (40 to 49 years, 72 percent), (50 to 59 years, 67 percent), and (60 to 69 years, 59 percent); and ends at (70 to 90 years, 45 percent). The curve labeled After two introductions starts from (18 to 39 years, 70 percent); passes through (40 to 49 years, 56 percent), (50 to 59 years, 49 percent), and (60 to 69 years, 42 percent); and ends at (70 to 90 years, 31 percent). The curve labeled After one introduction starts from (18 to 39 years, 34 percent); passes through (40 to 49 years, 25 percent), (50 to 59 years, 20 percent), and (60 to 69 years, 17 percent); and ends at (70 to 90 years, 12 percent). All data are approximate. A text reads, older age groups have poorer performance.

Return to FIGURE 17.3 Tests of recall

Extended description for FIGURE 17.4 Recall and recognition in adulthood

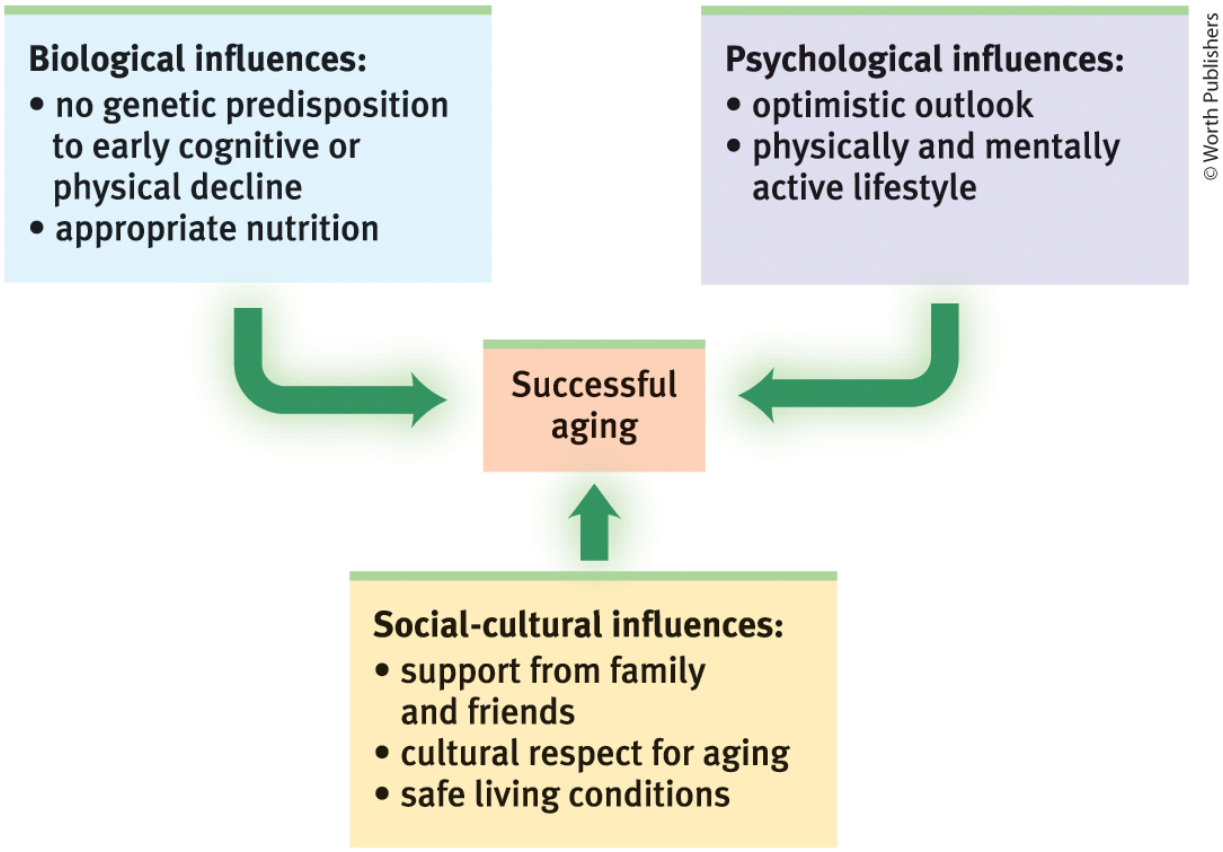


The horizontal axis represents age (years) and ranges from 20 to 70, in increments of 10. The vertical axis represents number of words

remembered and ranges from 0 to 24, in increments of 4. A red curve starts from (20, 21), declines to (30, 20), and rises to end at (60, 21.5). The curve is labeled, number of words *recognized* is stable with age. A green curve starts from (20, 14); passes through (30, 13.5), (40, 11), and (50, 11); and ends at (60, 7.5). The curve is labeled, number of words *recalled* declines with age. All data are approximate.

Return to FIGURE 17.4 Recall and recognition in adulthood

Extended description for FIGURE 17.6 We are social creatures



The horizontal axis represents hours spent with others the previous day and ranges from 0 to 8, in increments of 1. The vertical axis represents In the U.S., percentage reporting a lot of stress-free enjoyment and happiness the previous day and ranges from 0 to 80 percent, in increments of 10. A curve for ages 18 to 29 begins at 26 percent at 0 hours; passes through 24 percent at 1 hour, 35 percent at 2 hours, 32 percent at 3 hours, 36 percent at 4 hours, 40 percent at 5 hours, 46 percent at 6 hours, and 50 percent at 7 hours; and end at 46 percent at 8 hours. A curve for ages 65 plus begins at 44 percent at 0

hours; passes through 50 percent at 1 hour, 57 percent at 2 hours, 67 percent at 3 hours, 69 percent at 4 hours, 66 percent at 5 hours, 72 percent at 6 hours, and 71 percent at 7 hours; and ends at 70 percent at 8 hours. All data are approximate.

Return to FIGURE 17.6 We are social creatures

Extended description for FIGURE 17.7 Biopsychosocial influences on successful aging

The information presented is as follows:

Biological influences: No genetic predisposition to early cognitive or physical decline; appropriate nutrition.

Psychological influences: Optimistic outlook; physically and mentally active lifestyle.

Social-cultural influences: Support from family and friends; cultural respect for aging; safe living conditions.

These three boxes all point to a center box labeled, **Successful aging**.

The photo shows a person wearing headphones. A hearing specialist is observing her and sending tones to her ears with a machine. In the graph, the horizontal axis represents intensity of stimulus, and the vertical axis represents percentage of correct detections. A curve starts from 0 and rises steadily to 50 percent achieving absolute threshold. The curve moves forward to reach up to 100 percent. The area from low to absolute threshold is marked as subliminal stimuli.

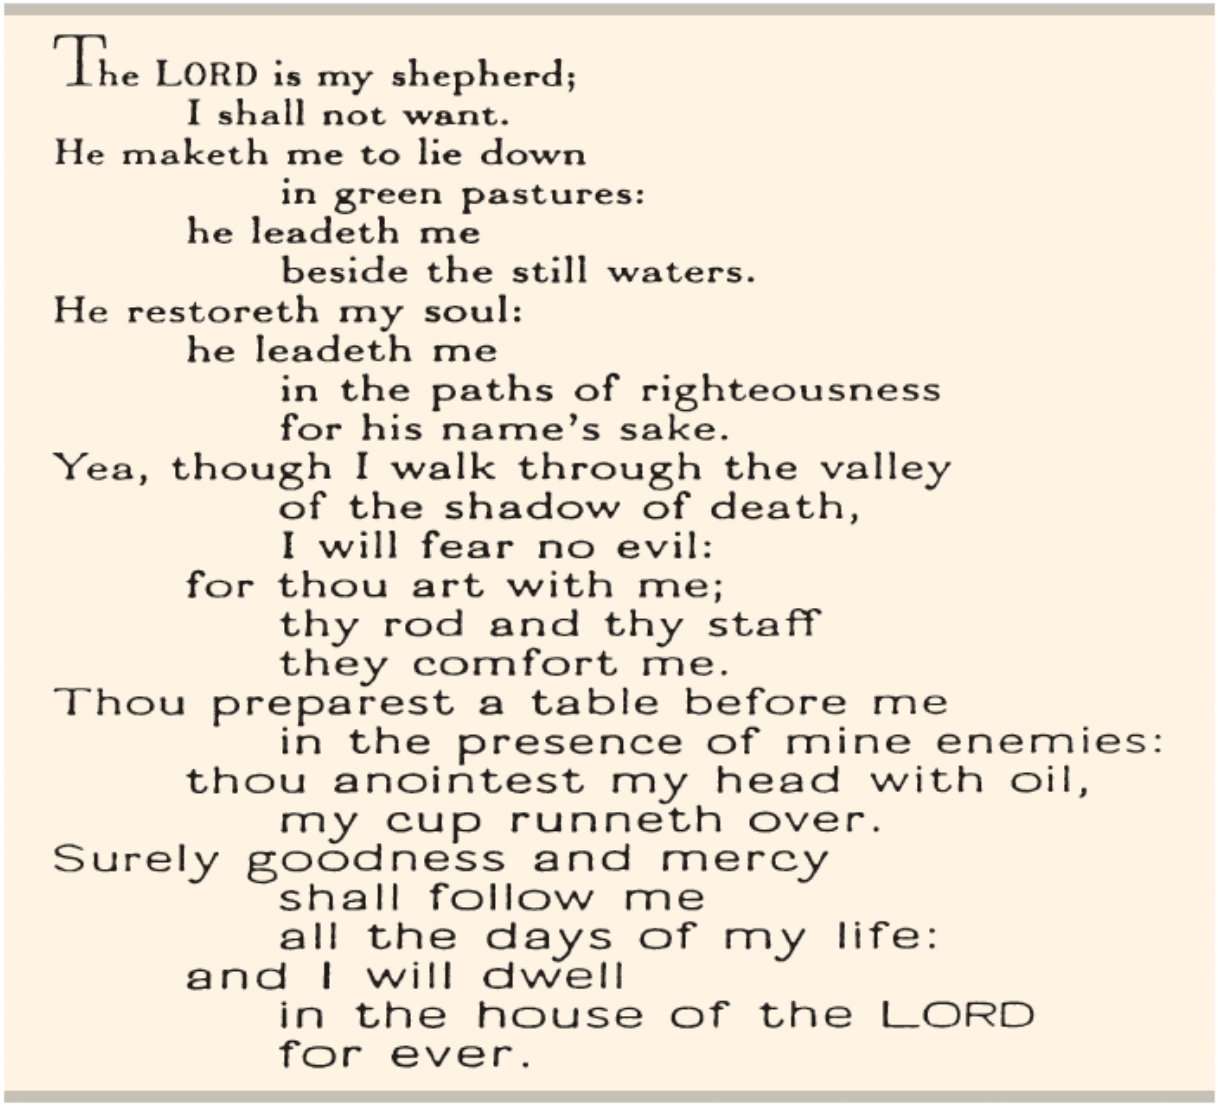
Return to FIGURE 18.2 Threshold detected

Extended description for Subliminal stimulation

© Worth Publishers

Text reads, Thinking Critically About: **Subliminal Sensation and Subliminal Persuasion. We can be affected by *subliminal* sensations** dash stimuli so weak that we don't consciously notice them.

Text in the top left panel reads, Researchers use **priming** to activate unconscious associations. Participant views slides of people and offers either favorable or unfavorable ratings of each person. **BUT** an instant before each slide appears, the trickster researcher subliminally flashes another image dash either pleasant (for example, kittens) or unpleasant (for example, a werewolf). An illustration shows a man viewing a desktop screen with kittens in the foreground and a man's face in the background. Another illustration after the word *or* shows the man viewing a desktop screen with a werewolf in the foreground and a man's face in the background. An illustration pointing to the first desktop screen shows two kittens, and another illustration pointing to the second desktop screen shows a werewolf. Also, an illustration shows a researcher noting down his observation. Accompanying text reads, Participants consciously perceive these images only as flashes of light.



Text in the bottom left panel reads, **Will participants' ratings of the faces be affected? Yes!** (Krosnick et al., 19 92). An arrow from an illustration of two kittens overlaid on a man's face points to text that reads, More **favorable** ratings of people. An arrow from an illustration of a werewolf overlaid on a man's face points to a text

that reads, More **unfavorable** ratings of people. Text at the bottom of the panel reads, Our two-track mind: Priming happens even though the viewer's brain does not have time to consciously perceive the flashed images. We may evaluate a stimulus even when we are not consciously aware of it. (Ferguson and Zayas, 2009).

Text in the right panel reads, **So, we can be *primed*, but can we be *persuaded* by subliminal stimuli,** for example to lose weight, stop smoking, or improve our memory? Three illustrations show a ribbon tied around a bathroom scale; a woman frowning because of the smoke coming from a cigarette; and a quiz paper with a 100 percent mark on it. Text below reads, Audio and video messages subliminally (without recipients' conscious awareness) announce. "I am thin," "Cigarette smoke tastes bad," and "I do well on tests. I have total recall of information." An arrow from this text points to a text box that reads, Results from 16 experiments (Greenwald et al., 19 91, 19 92) showed no powerful, enduring influence on behavior. Not one of the recordings helped more than placebo, which works only because we believe it will.

Return to Subliminal stimulation

Extended description for The difference threshold

The LORD is my shepherd;
I shall not want.
He maketh me to lie down
in green pastures:
he leadeth me
beside the still waters.
He restoreth my soul:
he leadeth me
in the paths of righteousness
for his name's sake.
Yea, though I walk through the valley
of the shadow of death,
I will fear no evil:
for thou art with me;
thy rod and thy staff
they comfort me.
Thou preparest a table before me
in the presence of mine enemies:
thou anointest my head with oil,
my cup runneth over.
Surely goodness and mercy
shall follow me
all the days of my life:
and I will dwell
in the house of the LORD
for ever.

The passage reads as follows:

The LORD is my shepherd;

I shall not want.

He maketh me to lie down

in green pastures:

he leadeth me

beside the still waters.

He restoreth my soul:

he leadeth me

in the paths of righteousness

for his name's sake.

Yea, though I walk through the valley

of the shadow of death,

I will fear no evil:

for thou art with me;

thy rod and thy staff

they comfort me.

Thou preparest a table before me

in the presence of mine enemies:

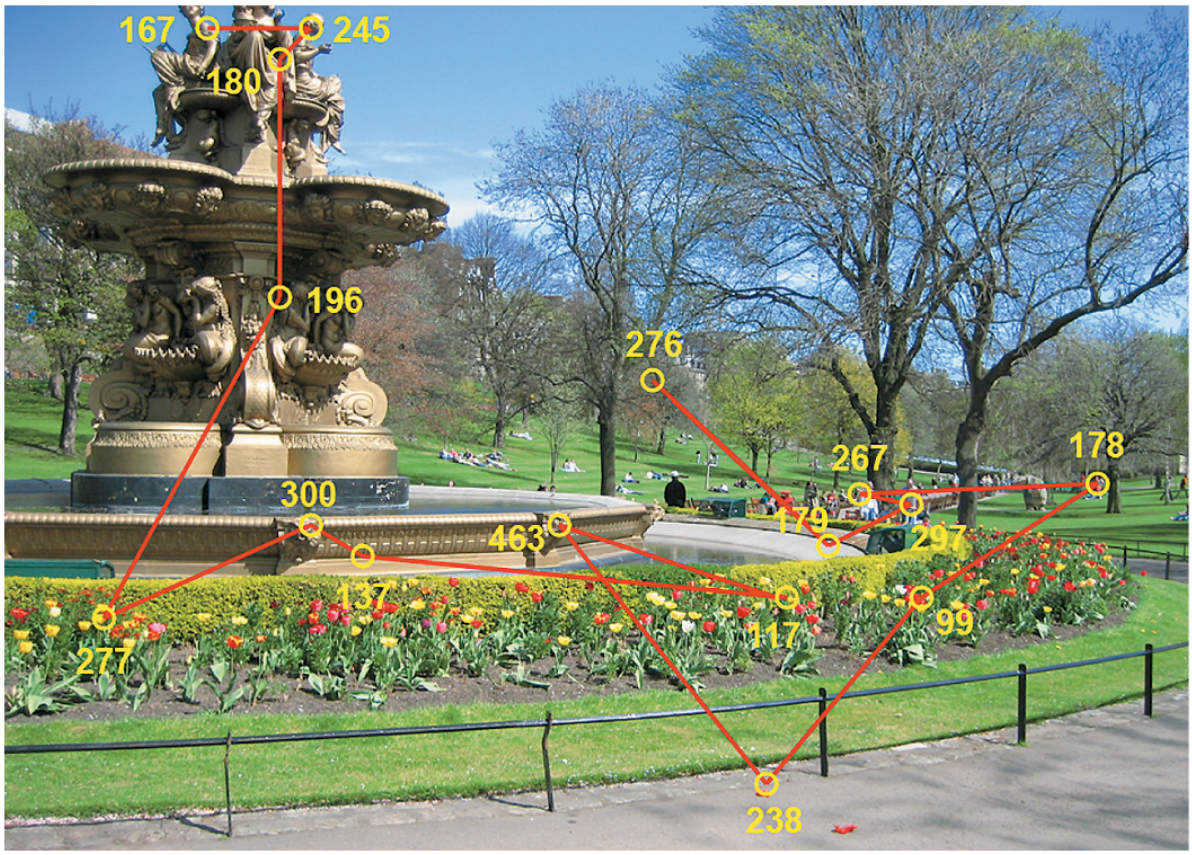
thou anointest my head with oil,

my cup runneth over.

Surely goodness and mercy

shall follow me

all the days of my life:



and I will dwell

In the house of the LORD

for ever.

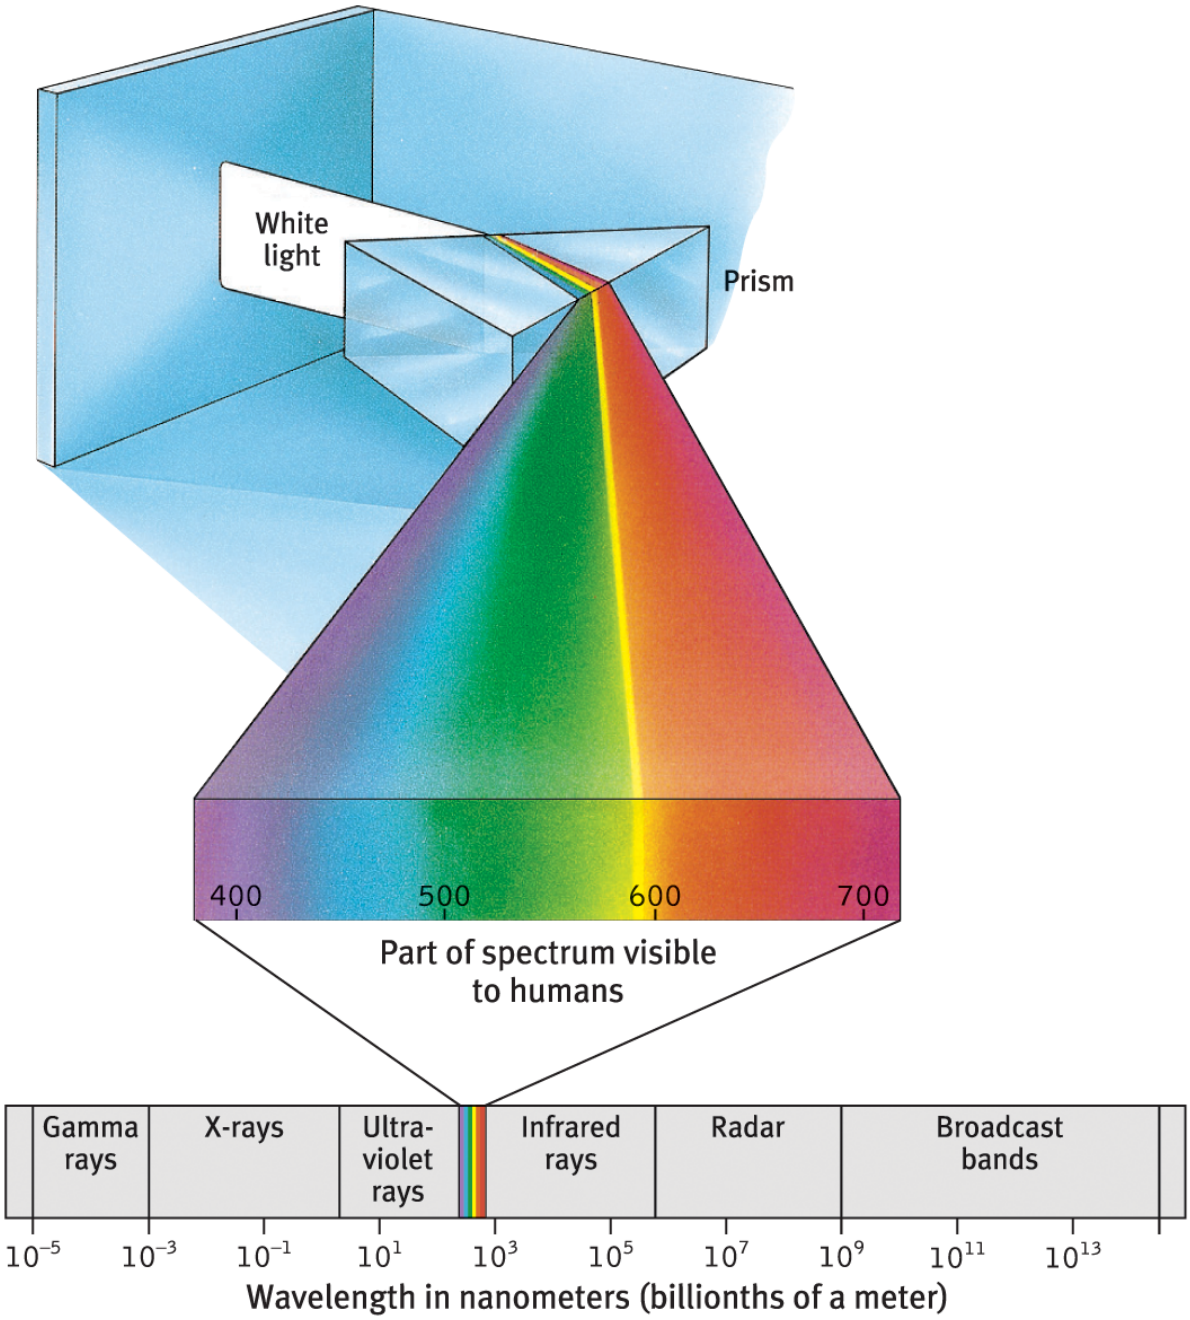
(b)

The illustration labeled (a) shows a woman’s face with a projector attached to a contact lens in her eye. The illustration labeled (b) shows a face in the first row, a triangle in the second row, a text that reads H B in the third row with no space between the letters H and B, and a text that reads BEER in the fourth row. There are fragments of a face next to the full face in the first row, fragments of a triangle next to the full triangle in the second row, fragments of the combined letters H B in the third row, and texts that read, PEER, PEEP, BEE and BE following BEER in the fourth row.

Return to FIGURE 18.4 Sensory adaptation: Now you see it, now you don't!

Extended description for FIGURE 18.5 Two examples of perceptual set

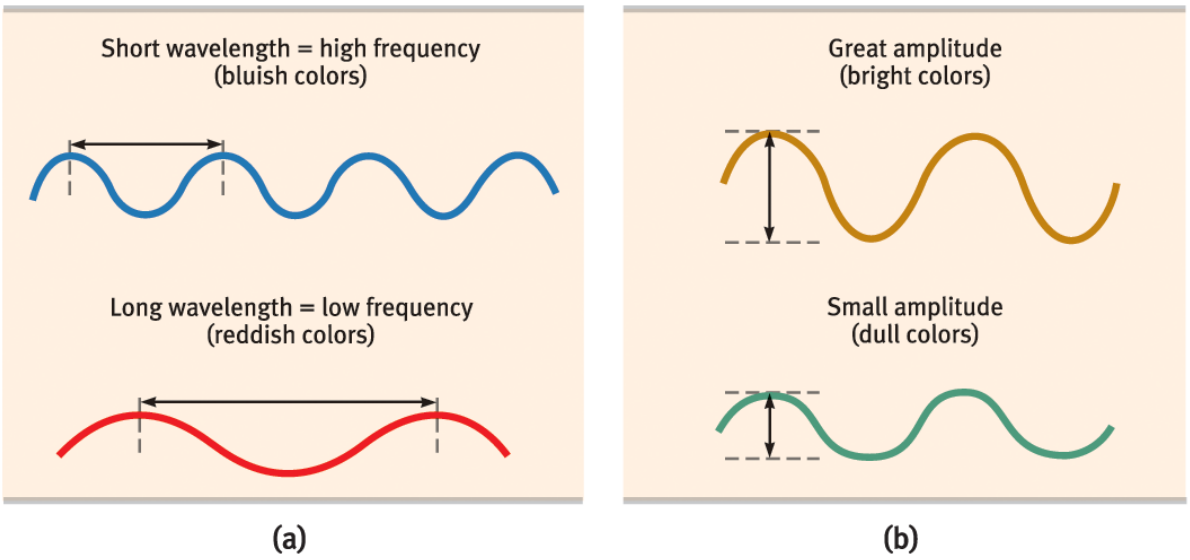


The side profile of a younger woman in a fur coat is more pronounced in illustration (a) while the side profile of an older woman is more pronounced in illustration (c). The illustration (b) can be viewed either as a younger woman or an older woman.

Illustration (d) shows the three horizontal blocks labeled as A, B, C and the three vertical blocks labeled as 12, 13, 14. The letter B and the number 13 are in the same intersecting block and can be perceived as a letter B if it is read from left to right or a number 13 if it is read from top to bottom.

Return to FIGURE 18.5 Two examples of perceptual set

Extended description for FIGURE 19.1 The wavelengths we see



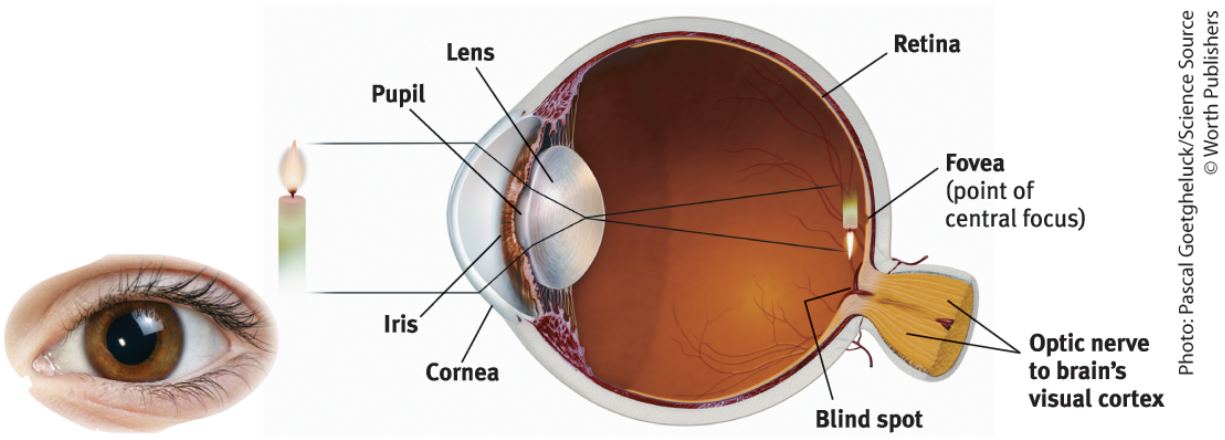
© Worth Publishers

White light reflects through a prism as a spectrum of colors: violet, indigo, blue, green, yellow, orange, and red. The spectrum of colors reflected has a scale below captioned, Part of spectrum visible to humans, and is labeled 400 at violet, 500 at green, 600 at yellow, and 700 at red. This scale leads to a small portion of another scale labeled wavelength in nanometers (billionths of a meter), which has the following values: 10 to the power of negative 5, 10 to the power of negative 3, 10 to the power of negative 1, 10 to the power of 1, 10 to the power of 3, 10 to the power of 5, 10 to the power of 7, 10 to the power of 9, 10 to the power of 11, and 10 to the power of 13. The scale reads as follows: Gamma rays, between 10 to the power of negative 5 and 10 to the power of negative 3; X-rays, between 10 to the power of negative 3 and 10 to the power of 1; Ultraviolet rays, between 10 to the power of 1 and 10 to the power of 3; reflected spectrum falls in this category, occupying approximately one-fourth of the total wavelength of ultraviolet rays; Infrared rays, between 10 to the power of 3 and 10 to the power of 5; Radar, between 10 to the power of 7 and 10 to the power of 9; and Broadcast bands, between 10 to the power of 11 and 10 to the power of 13.

Return to FIGURE 19.1 The wavelengths we see

Extended description for FIGURE 19.2 The physical properties of waves

© Worth Publishers

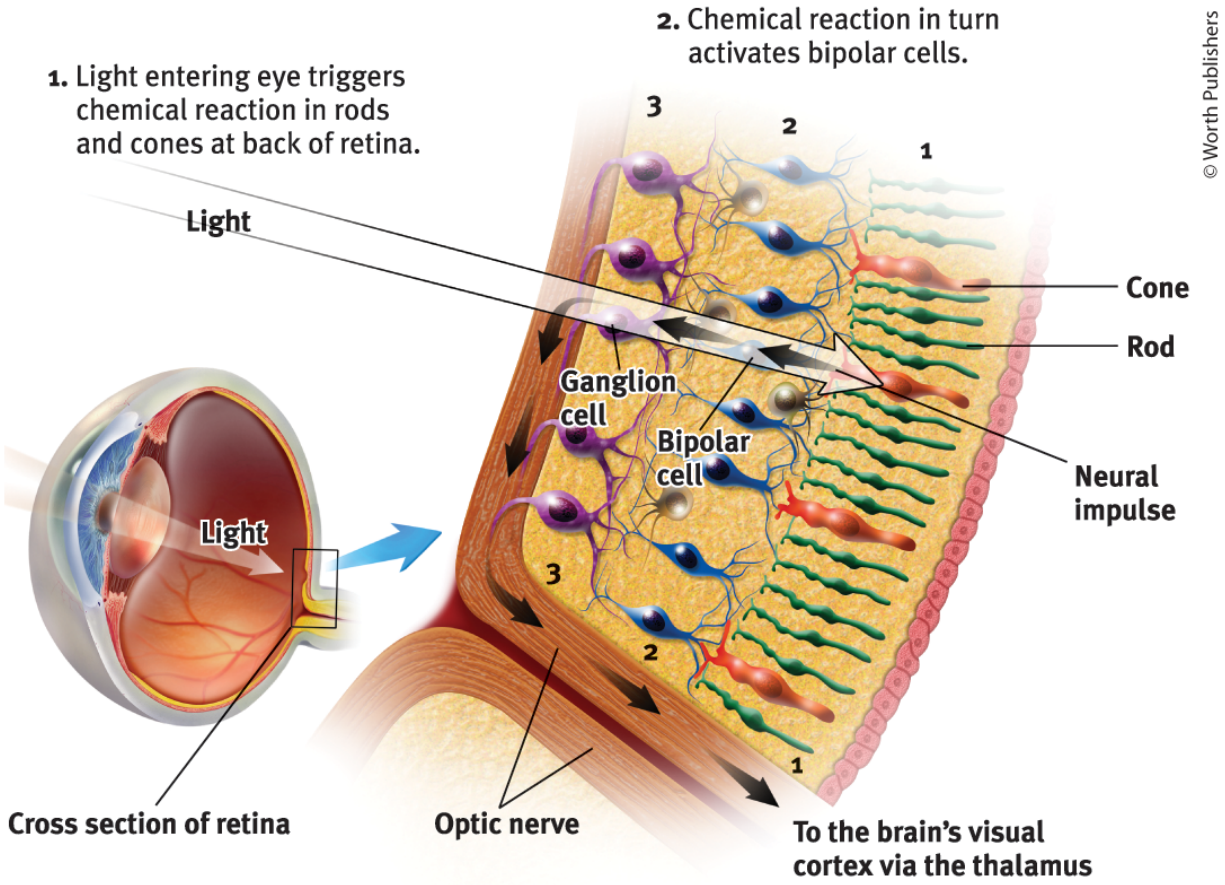


Part (a) shows two waves. The first wave has four peaks, and the distance between the first two peaks is marked with a double-headed arrow. The distance between the peaks is small. A text reads, Short wavelength equals high frequency (bluish colors). The second wave has two peaks, and the distance between the first two peaks is marked with a double-headed arrow. The distance between the two peaks is large and longer compared to the first wave. Text reads, Long wavelength equals low frequency (reddish colors).

Part (b) shows two waves. The first wave has two peaks and two troughs, and the distance between the peak and the trough is

marked with a double-headed arrow. The distance between the peak and the trough is long. Text reads, Great amplitude (bright colors). The second wave also has two peaks and two troughs, and the distance between the peak and the trough is marked with a double-headed arrow. The distance between the peak and the trough is short compared to the first wave. Text reads, Small amplitude (dull colors).

Return to FIGURE 19.2 The physical properties of waves

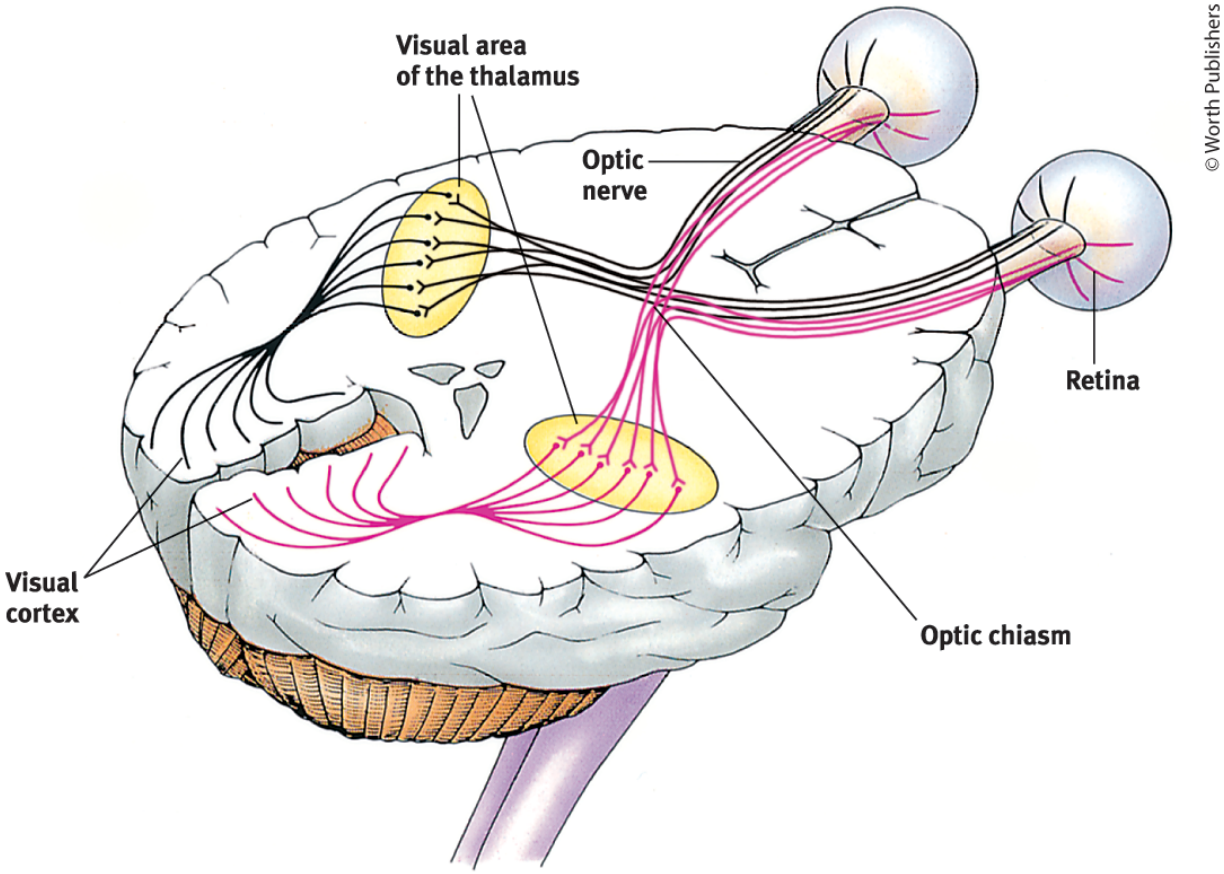


Extended description for FIGURE 19.3 The eye

The illustration shows a lit candle placed in front of a human eye. The light rays reflected from the candle pass through the Cornea, the Iris, and the Pupil, after which the rays hit the Lens in the eye. The lens focuses the light rays to form an inverted image of the candle on the Fovea (point of central focus), marked in the Retina. A Blind spot and the Optic nerve to the brain's visual cortex are labeled below the Fovea.

Return to FIGURE 19.3 The eye

Extended description for FIGURE 19.4 The retina's reaction to light

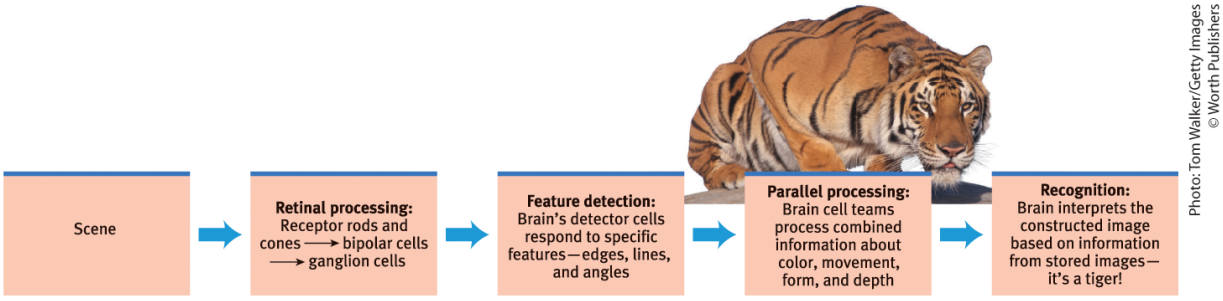


The illustration shows a sectional view of an eye with light hitting the cross-section of the retina. An enlarged view of the cross-section of the retina shows light reaching the rods and cones (1). The neural impulse passes from rods and cones to a Bipolar cell (2) to a

Ganglion cell (3) to an Optic nerve that carries the impulse to the brain's visual cortex via the thalamus. The steps are as follows: 1. Light entering eye triggers chemical reaction in rods and cones at back of retina. 2. Chemical reaction in turn activates bipolar cells. 3. Bipolar cells then activate the ganglion cells, whose combined axons form the optic nerve. This nerve transmits information (via the thalamus) to the brain's visual cortex.

Return to FIGURE 19.4 The retina's reaction to light

Extended description for FIGURE 19.7 Pathway from the eyes to the visual cortex



© Worth Publishers

The optic nerves carrying information from the left and right retina to the visual area of the thalamus cross paths at the optic chiasm, at which point the nerves carrying information from the left retina run to the right visual area of the thalamus and the nerves carrying information from the right retina run to the left visual area of the

thalamus. The nerves end at the visual cortex, located at the back of the brain.

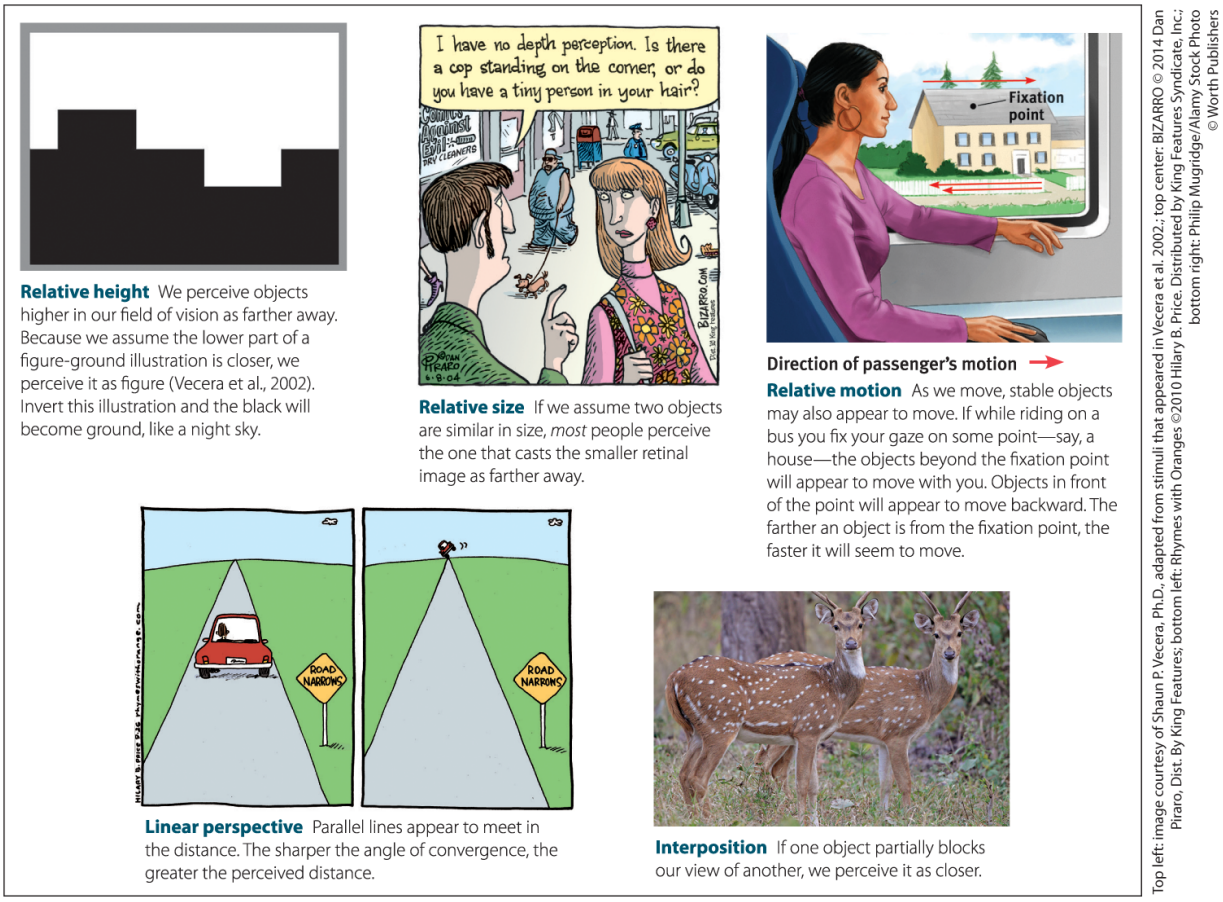
Return to FIGURE 19.7 Pathway from the eyes to the visual cortex

Extended description for FIGURE 19.11 A simplified summary of visual information processing

The flowchart shows a series of five stages connected by arrows, which read as follows. Stage 1, **Scene**. Stage 2, **Retinal processing**: From receptor rods and cones to bipolar cells to ganglion cells. Stage 3, **Feature detection**: Brain's detector cells respond to specific features dash edges, lines, and angles. Stage 4, **Parallel processing**: Brain cell teams process combined information about color, movement, form, and depth. Stage 5, **Recognition**: Brain interprets the constructed image based on information from stored images - it's a tiger! In the background, a photo shows a crouching tiger.

Return to FIGURE 19.11 A simplified summary of visual information processing

Extended description for FIGURE 19.16 Gibson and Walk's visual cliff



© Worth Publishers

The woman is at the transparent end of the table crouched down with arms extended. The baby is on the patterned end of the table attempting to crawl to her. Visually the table appears to have a drop-off due to the application of a checkerboard pattern at the top, face, and bottom of the table.

Return to FIGURE 19.16 Gibson and Walk's visual cliff

Extended description for FIGURE 19.18 Monocular depth cues

Relative height We perceive objects higher in our field of vision as farther away. Because we assume the lower part of a figure-ground illustration is closer, we perceive it as figure (Vecera et al., 2002). Invert this illustration and the black will become ground, like a night sky.

Relative size If we assume two objects are similar in size, *most* people perceive the one that casts the smaller retinal image as farther away.

Relative motion As we move, stable objects may also appear to move. If while riding on a bus you fix your gaze on some point—say, a house—the objects beyond the fixation point will appear to move with you. Objects in front of the point will appear to move backward. The farther an object is from the fixation point, the faster it will seem to move.

Linear perspective Parallel lines appear to meet in the distance. The sharper the angle of convergence, the greater the perceived distance.

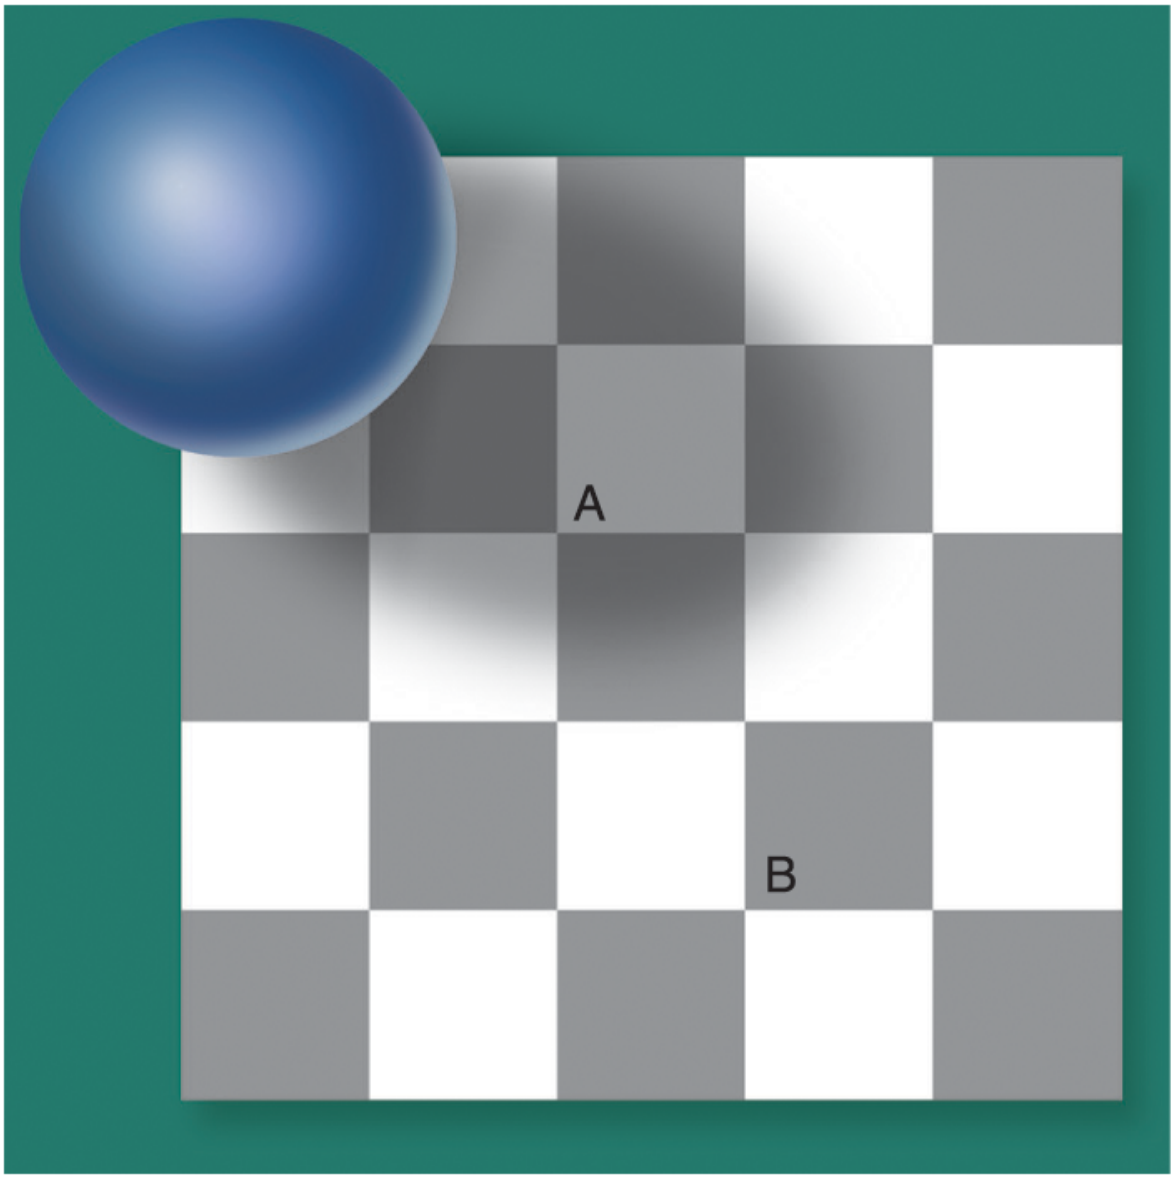
Interposition If one object partially blocks our view of another, we perceive it as closer.

Top left: image courtesy of Shaun P. Vecera, Ph.D., adapted from stimuli that appeared in Vecera et al. 2002.; top center: BIZARRO © 2014 Dan Piraro, Dist. By King Features; bottom left: Rhymes with Oranges ©2010 Hilary B. Price. Distributed by King Features Syndicate, Inc.; bottom right: Philip Mugridge/Alamy Stock Photo © Worth Publishers

An illustration in the first part shows a dark wall against a blank background. The wall is uneven, part of the wall rises up and comes back to the same level and then lowers down and comes back to the same level. Text below reads, **Relative height.** We perceive objects higher in our field of vision as farther away. Because we assume the lower part of a figure-ground illustration is closer, we perceive it as

figure (Vecera et al., 2002). Invert this illustration and the black will become ground, like a night sky.

A cartoon in the second part shows a man speaking to a woman on a sidewalk. A speech bubble from the man reads, I have no depth perception. Is there a cop standing on the corner, or do you have a tiny person in your hair? The cartoon shows a police officer standing in the corner, right above the woman's head. There is another man walking his dog. Text below reads, **Relative size.** If we assume two objects are similar in size, most people perceive the one that casts the smaller retinal image as farther away.



An illustration in the third part shows a woman sitting inside a bus and looking outside the window. There is a house on the other side of the bus. A dot is marked on the roof of the house and labeled fixation point. Arrows are marked along the roof of the house and on the pathway of the house. The arrow along the roof points right whereas the two arrows on the pathway points left. Text below the illustration reads, **Direction of passenger's motion.** An arrow after the text points right. Further text below reads, **Relative motion.** As we move, stable objects may also appear to move. If while riding on a bus you fix your gaze on some point—say, a house—the objects beyond the fixation point will appear to move with you. Objects in front of the point will appear to move backward. The farther an object is from the fixation point, the faster it will seem to move.

Two illustrations in the fourth part show a narrow road with a lawn on either side. There is a signboard that reads, Road Narrows. The first illustration shows a car traveling on a narrow road, and the second illustration shows a car toppling down the edge of the narrow road. Text below reads, **Linear perspective.** Parallel lines appear to meet in the distance. The sharper the angle of convergence, the greater the perceived distance.

A photo in the fifth part shows two deer standing next to each other, with one partly blocking the other from view. Text below reads, **Interposition**. If one object partially blocks our view of another, we perceive it as closer.

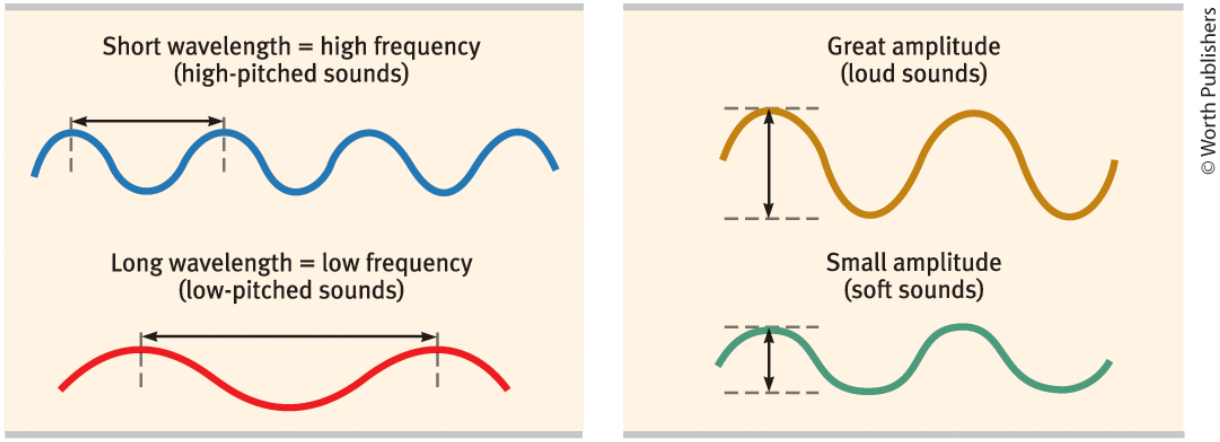
Extended description for FIGURE 19.21 Relative luminance



© Worth Publishers

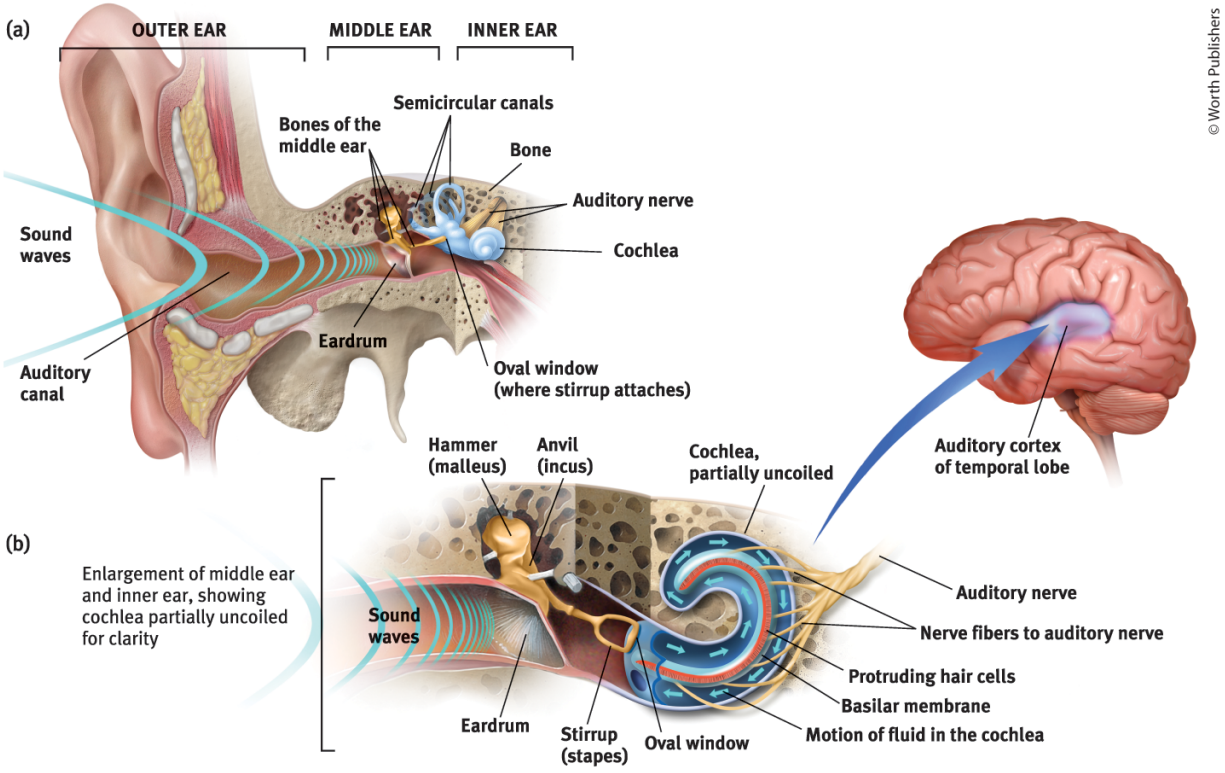
Two squares on the board, one white at the top middle in the shadowed region labeled A and one black at the bottom right in the

lit region labeled B, are identical in color. However, the visual illusion makes the square labeled A perceived as brighter than the square labeled B because of its surrounding context.

Return to FIGURE 19.21 Relative luminance

Extended description for FIGURE 20.1 The physical properties of waves

© Worth Publishers



Part (a) shows two waves. The first wave has four peaks, and the distance between the first two peaks is marked with a double-headed arrow. The distance between the peaks is small. A text reads, Short wavelength equals high frequency (high-pitched sounds). The second wave has two peaks, and the distance between the first two peaks is marked with a double-headed arrow. The distance between the two peaks is large and longer compared to the first wave. A text reads, Long wavelength equals low frequency (low-pitched sounds).

Part (b) shows two waves. The first wave has two peaks and two troughs, and the distance between the peak and the trough is marked with a double-headed arrow. The distance between the peak

and the trough is long. A text reads, Great amplitude (loud sounds). The second wave also has two peaks and two troughs, the distance between the peak and the trough is marked with a double-headed arrow. The distance between the peak and the trough is short. A text reads, Small amplitude (soft sounds).

Return to FIGURE 20.1 The physical properties of waves

Extended description for FIGURE 20.2 Hear here: How we transform sound waves into nerve impulses that our brain interprets

The section labeled (a) shows the cross-sectional view of an ear with the outer ear, middle ear, and inner ear labeled. Sound waves are depicted traveling through the auditory canal in the outer ear to the eardrum in the middle ear. Bones of the middle ear and semicircular canals are marked and labeled in the middle ear. The Auditory nerve, Cochlea, and Oval window (where stirrup attaches) are marked and labeled in the inner ear.

The section labeled (b) shows an enlargement of the middle ear and inner ear, showing the cochlea partially uncoiled for clarity. Sound waves are depicted traveling to the eardrum. The Hammer (malleus) and Anvil (incus), present above the eardrum, are connected to the Stirrup (stapes), which is attached to the oval window of the inner ear to meet the Cochlea (partially coiled). Clockwise arrows indicate the motion of fluid in the cochlea, which is surrounded by the Basilar membrane having protruding hair cells. Several nerve fibers attached to the hair cells unite to reach the auditory nerve. An arrow points to the Auditory cortex of the temporal lobe in the human brain.

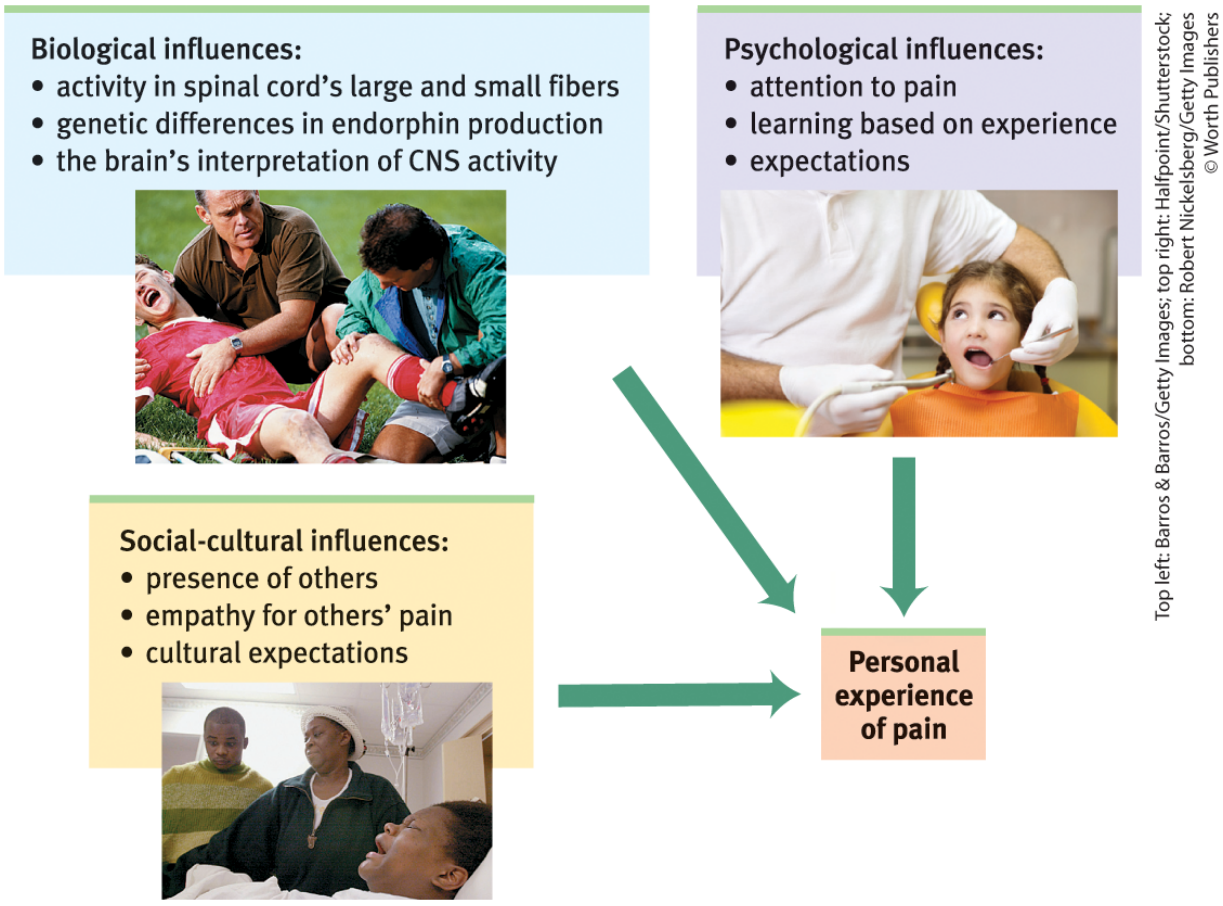
Extended description for FIGURE 20.4

Hardware for hearing

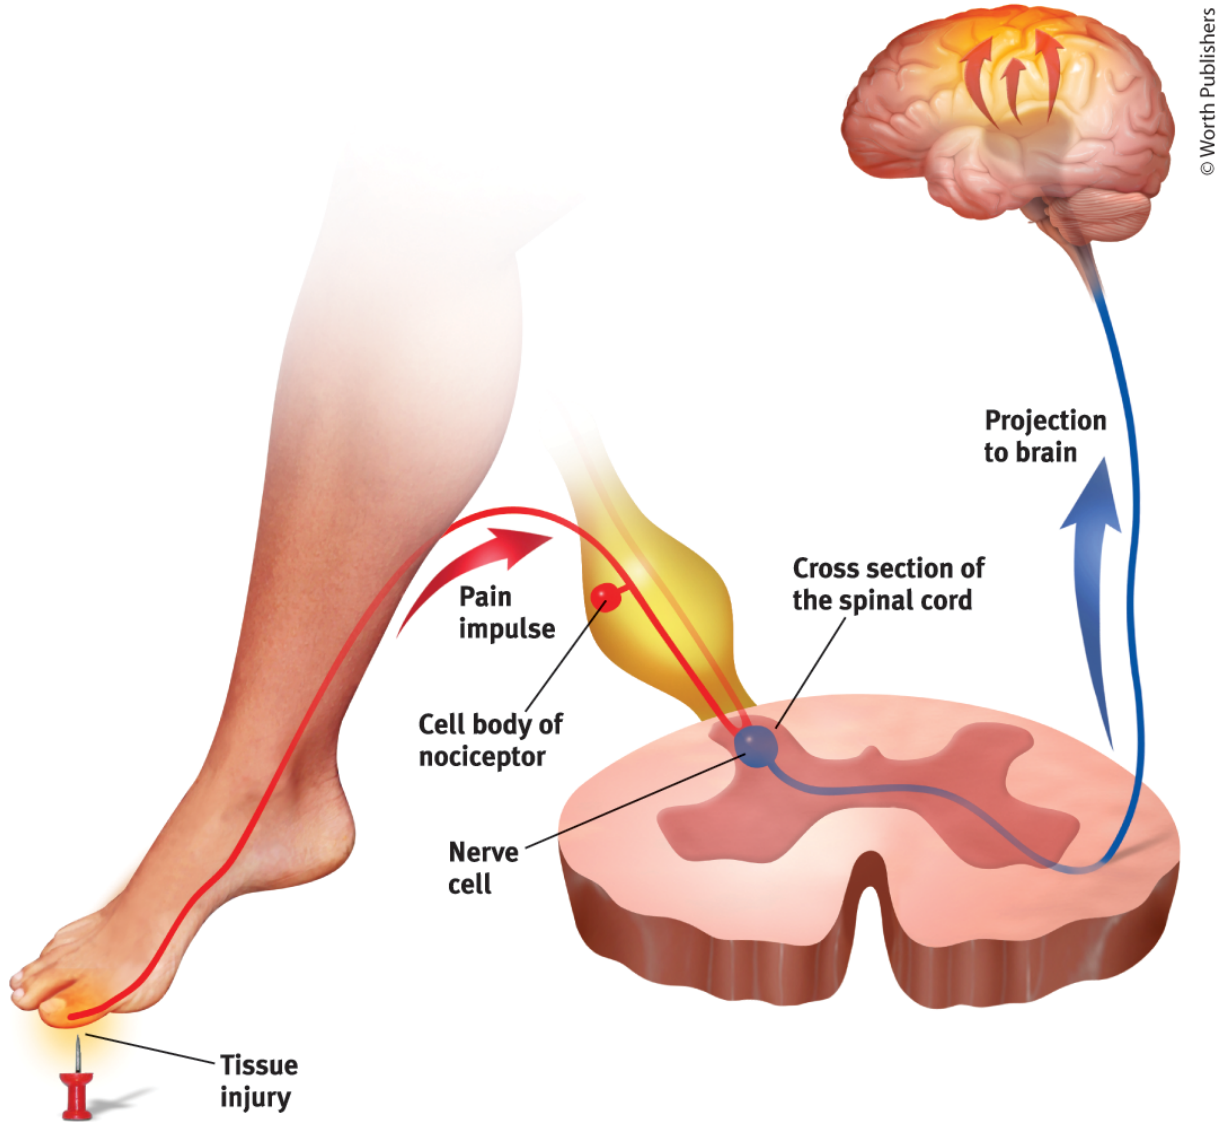


© Worth Publishers

The illustration shows a speech processor placed on the outer side of the pinna. A wire attaches the speech processor to a transmitter placed on the side of the head, above the ear. A receiver slash stimulator is connected to the transmitter, from which a wire sends sound to an electrode placed within the cochlea of the ear.

Return to FIGURE 20.4 Hardware for hearing

Extended description for FIGURE 20.6 Biopsychosocial approach to pain



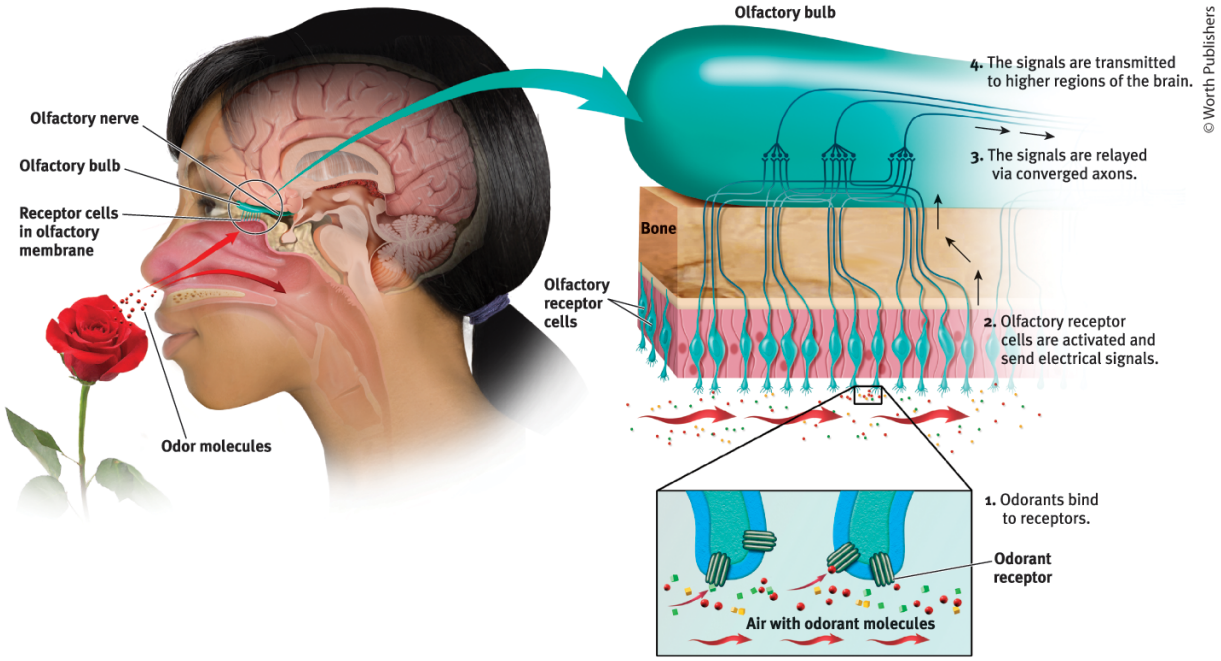
Top left: Barros & Barros/Getty Images; top right: Halfpoint/Shutterstock; bottom: Robert Nickelsberg/Getty Images
© Worth Publishers

Three text boxes with photos point to a smaller text box at the bottom right that reads, Personal experience of pain. The top left box shows **Biological influences**: activity in spinal cord's large and small fibers, genetic differences in endorphin production, and the brain's interpretation of C N S activity. A photo shows two people helping a wounded football player who is in pain. The bottom left

box shows **Social-cultural influences**: presence of others, empathy for others' pain, and cultural expectations. A photo shows a hospitalized elderly woman crying in pain. There are two people beside her. The top right box shows **Psychological influences**: attention to pain, learning based on experience, and expectations. A photo shows a young girl being treated by a dentist.

Return to FIGURE 20.6 Biopsychosocial approach to pain

Extended description for FIGURE 20.7 The pain circuit



The illustration shows a human leg stepping on a thumbtack leading to a tissue injury that sends a pain impulse from the toe to the cross-

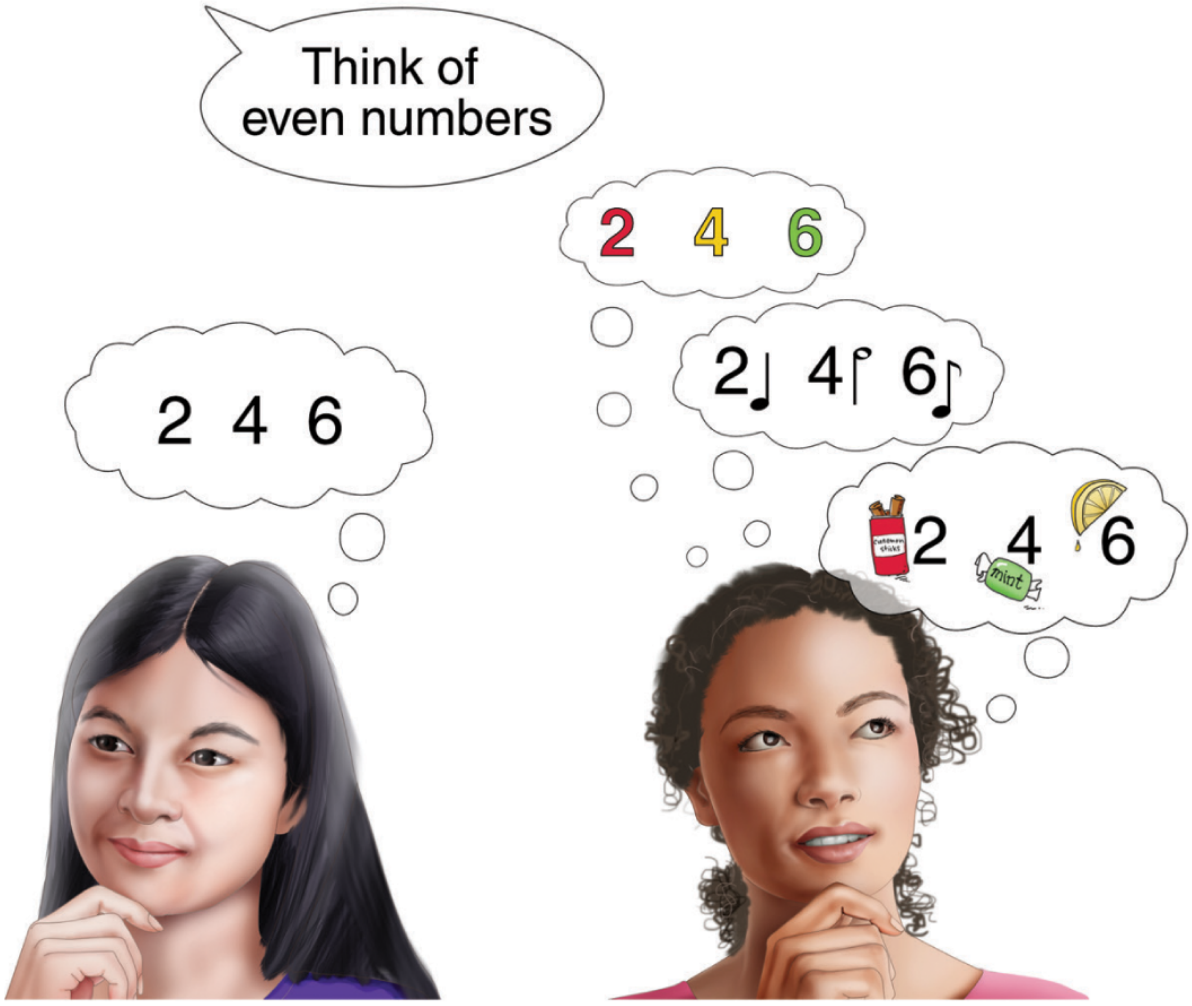
section of the spinal cord via the cell body of the nociceptor. The nerve cell receives the impulse in the cross-section of the spinal cord and projects the pain impulse to the brain. Arrows are depicted in the brain pointing from the brain stem to the top of the head.

Return to FIGURE 20.7 The pain circuit

Extended description for FIGURE 20.8 The sense of smell

The illustration shows the lateral view of a person with the brain highlighted. The person smells a rose. Odor molecules from the rose travel up the nose to the receptor cells in the olfactory membrane and then to the olfactory bulb and the olfactory nerve. An enlarged view of the olfactory bulb shows the following steps:

1: Odorants bind to receptors. An illustration shows the odorant molecules from the air binding to the odorant receptor.



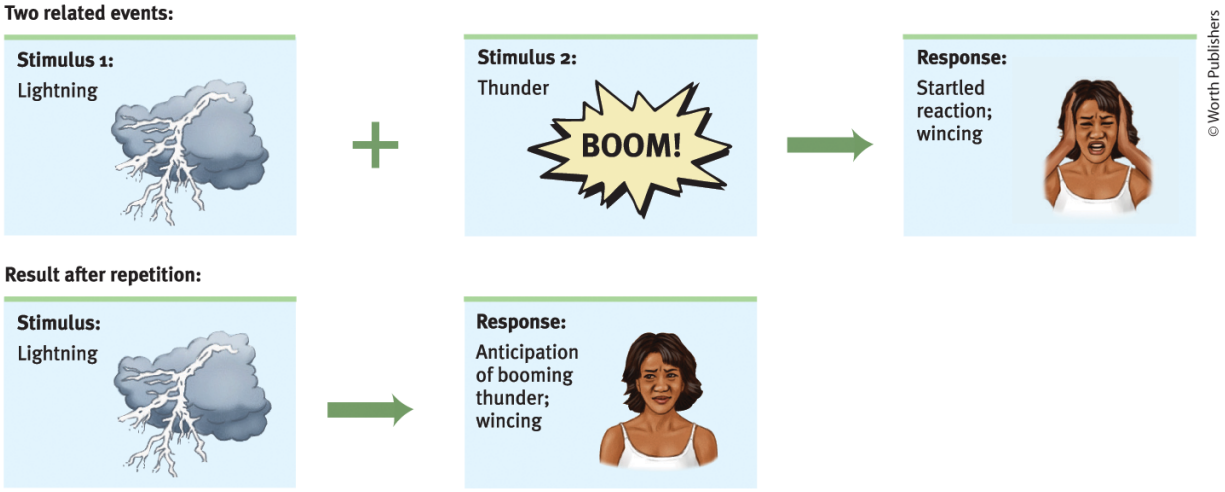
2: Olfactory receptor cells are activated and send electrical signals. An illustration shows the olfactory receptor cells ascending through a tissue layer and sending impulses up nerves through bone in the third level.

3: The signals are relayed via converged axons. An illustration shows the axons converging into a single nerve, the olfactory nerve.

4: The signals are transmitted to higher regions of the brain.

Return to FIGURE 20.8 The sense of smell

Extended description for FIGURE 20.11 Synesthesia's symphony



© Worth Publishers

The illustration shows two persons, one without synesthesia and the other with synesthesia. A speech bubble at the top reads, Think of even numbers. A thought bubble above the person without

synesthesia reads, 2 4 6. Three thought bubbles above the person with synesthesia read, 2 4 6 in three different colors; 2 4 6 with a musical note beside each number; and 2 4 6 with a different type of food (a candy, a mint, a lemon) beside each number.

Return to FIGURE 20.11 Synesthesia's symphony

Extended description for FIGURE 21.1 Classical conditioning

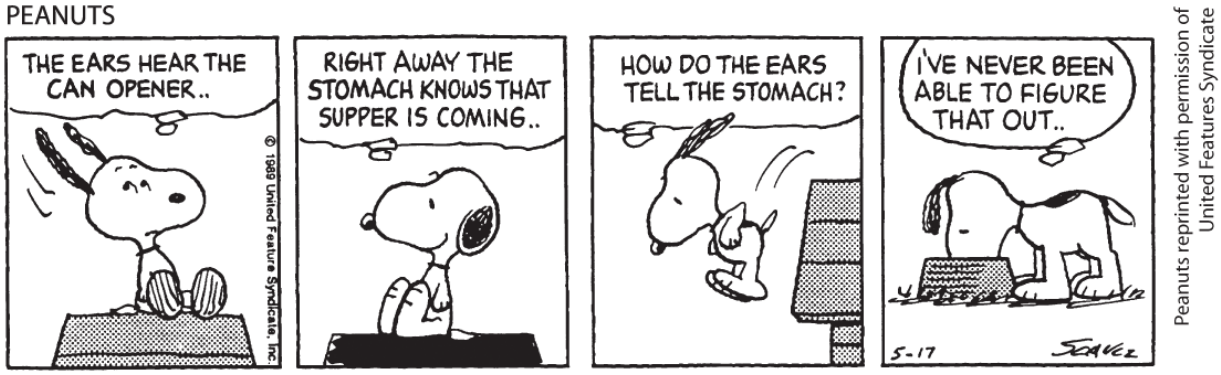
Extended description for FIGURE 21.4 Pavlov's classic experiment

© Worth Publishers

The top two panels are titled, **Before Conditioning**. The left panel shows a bowl of food placed before a salivating dog. Text beside the bowl reads, U S (food in mouth). An arrow points toward the dog's mouth. Text below the dog's mouth reads, U R (salivation). Text below the panel reads, An unconditioned stimulus (U S) produces an unconditioned response (U R).

The right panel shows a vibrating tuning fork placed before the dog. Text near the fork reads, N S (tone). An arrow points toward the dog's mouth. Text under the dog's mouth reads, No salivation. Text



below the panel reads, A neutral stimulus (N S) produces no salivation response.

The bottom left panel is titled, **During Conditioning**. It shows both the vibrating tuning fork and bowl of food placed before a salivating dog. Text near the fork reads, N S (tone). Text on top of the bowl reads, U S (food in mouth). An arrow points toward the dog's mouth. Text under the dog's mouth reads, U R (salivation). Text below the panel reads, The U S is repeatedly presented just after the N S. The U S continues to produce a U R.

The bottom right panel is titled, **After Conditioning**. It shows the vibrating tuning fork placed before a salivating dog. Text near the tuning fork reads, C S (tone). An arrow points toward the dog's mouth. Text under the dog's mouth reads, C R (salivation). Text below the panel reads, The previously neutral stimulus alone now produces a conditioned response (C R), thereby becoming a conditioned stimulus (C S).

Extended description for Effects of

viewing media violence

© Worth Publishers

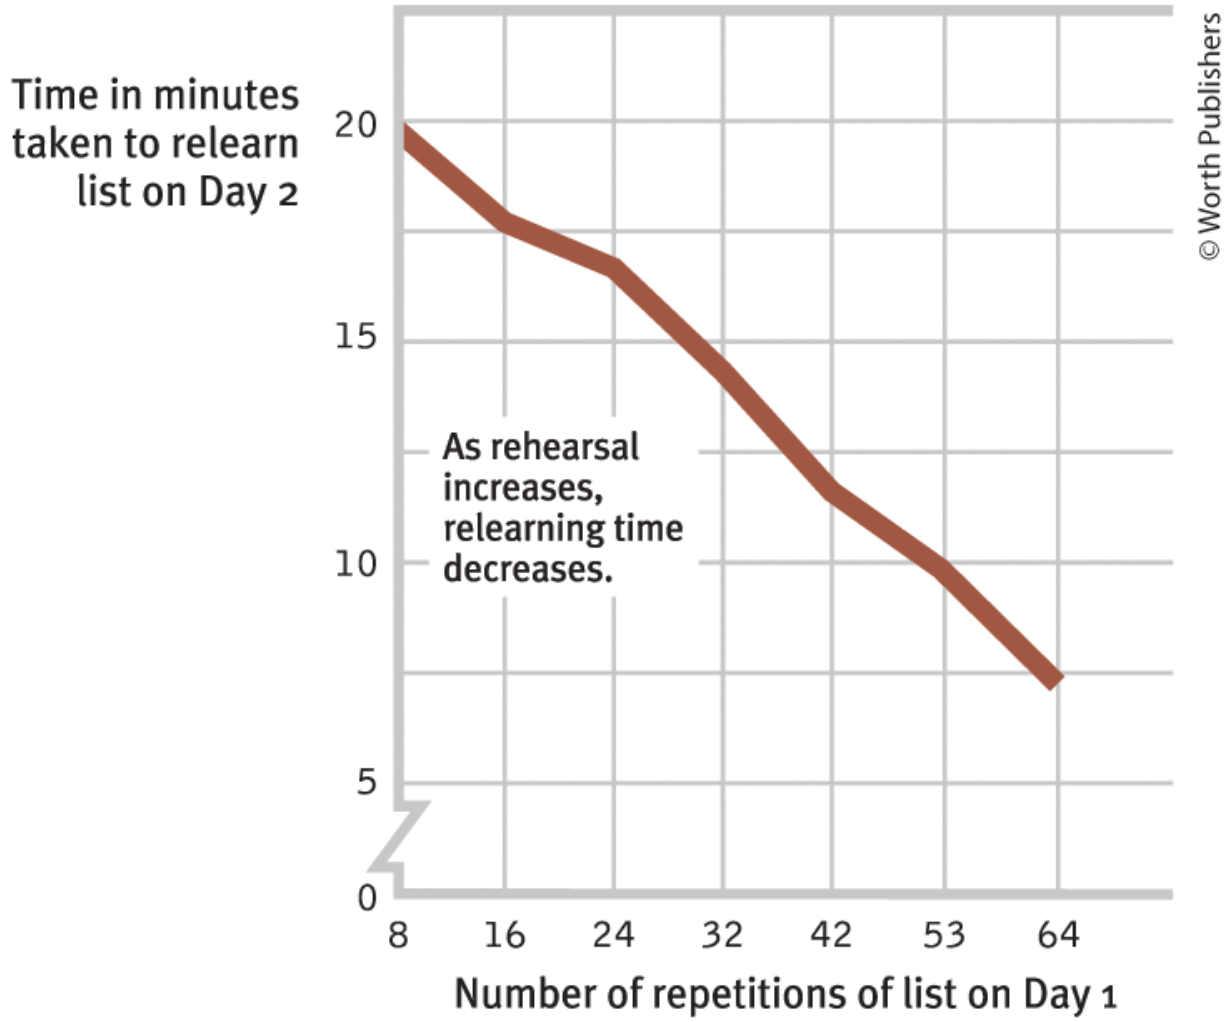
In the top panel, three side-by-side illustrations show the effects of the introduction of T V and also of heavy exposure to media violence. The first illustration shows an old-fashioned console T V with the caption, *Introduction of T V, 19 57 to 19 74*. This is followed by a double-headed arrow, indicating a two-way relationship, then an image of a gravestone. The caption below the gravestone reads, *Doubling of homicide rate in U.S. and Canada* (Centerwall, 19 89). The second illustration shows a T V with the caption, *Introduction of T V for White South Africans in 19 75*. This is followed by a double-headed arrow, indicating a two-way relationship, then an image of a gravestone. The caption below the gravestone reads, *Near-doubling of homicide rate in South Africa* (Centerwall, 19 89). The third illustration shows a T V screen from which a hooded man holding a bloody axe, a hand pointing a gun, and two people fighting are emerging. The caption reads, *Heavy exposure to media violence for U.S. 9- to 11-year-olds*. This is followed by a double-headed arrow, indicating a two-way relationship, then the text, *Increased fighting, and more violent behavior later as teens* (Boxer et al. 2009, Gentile et al. 2011, Gentile and Bushman, 2012). Text below the three illustrations reads, **BUT, CORRELATION DOES NOT EQUAL CAUSATION! *Experimental* studies have also found that media violence viewing can cause aggression:** Viewing violence (compared to entertaining nonviolence), right-facing arrow, participants react more cruelly when provoked. (Effect is strongest if the violent person is attractive, the violence seems justified and realistic, the act goes unpunished, and the viewer does not see pain or harm caused.)

In the second panel, the heading reads, **What prompts the *violence-viewing* effect?** Two sections show imitation and desensitization, respectively. The first section has the heading, **1. Imitation**. The top of the section has an illustration that shows a group of children watching two people fighting on a T V and later imitating it. Text below reads, Watching violent cartoons, right-facing arrow, Sevenfold increase in violent play (Boyatzis et al. 19 95). The bottom of the first section, still under the Imitation heading, shows a switched-off T V and a group of children sitting beside it reading and playing games. Text below reads, Limited exposure to violent programs, right-facing arrow, Reduced aggressive behavior (Christakis et al. 2013). The second section has the heading, **2. Desensitization**. The first illustration shows the earlier image of the axe-wielding man, the hand pointing a gun, and the two men fighting emerging from the screen. But the image is replicated five times, indicating multiple views of these images. The second illustration shows a man looking at his phone with the earlier-described screen on the wall in front of him. Under these illustrations, the text reads, Prolonged exposure to violence, right-facing arrow, Viewers are later indifferent (desensitized) to violence on T V or in real life (Fanti et al. 2009; Jin et al., 2018; Rule and Ferguson, 19 86). The bottom of the second section, still under the Desensitization heading, has an illustration showing the man holding his phone, with one of his eyes looking at three T V screens with the image of a hand holding a gun and three large Xs behind the gun. His other eye is focused on a woman holding crutches who

has stumbled and fallen. A thought bubble from the man reads, meh. Text below reads, Adult males spent 3 evenings watching sexually violent movies, right-facing arrow. Viewers became progressively less bothered by the violence shown. Compared to a control group, they expressed less sympathy for domestic violence victims and rated victims' injuries as less severe (Mullin and Linz, 19 95). Text below reads, violent moviegoers, right-facing arrow, less likely to help. Nonviolent movie goers, right-facing arrow, more likely to help (Bushman and Anderson, 2009).

A bulleted list at the bottom of the infographic reads,

Bullet item 1: **A P A Task Force on Violent Media (2015)** found that the "research demonstrates a consistent relation between violent video game use and increases in aggressive behavior, aggressive cognitions, and aggressive effect, and decreases in prosocial behavior, empathy, and sensitivity to aggression."



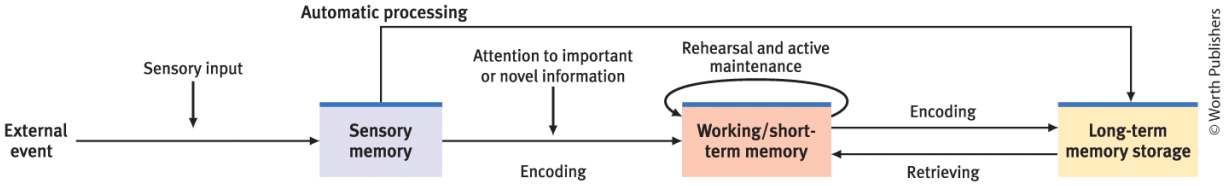
Bullet item 2: **American Academy of Pediatrics (2009)** has advised pediatricians that "media violence can contribute to aggressive behavior, desensitization to violence, nightmares, and fear of being harmed."

Text below reads, **Critics** suggest that these statements may ignore some weakness in media violence research, such as reliability and the size of the effect. They also note that some places, such as Japan,

have similarly violent media but much less violent behavior (Elson et al., 2019; Ferguson et al., 2020).

Return to Effects of viewing media violence

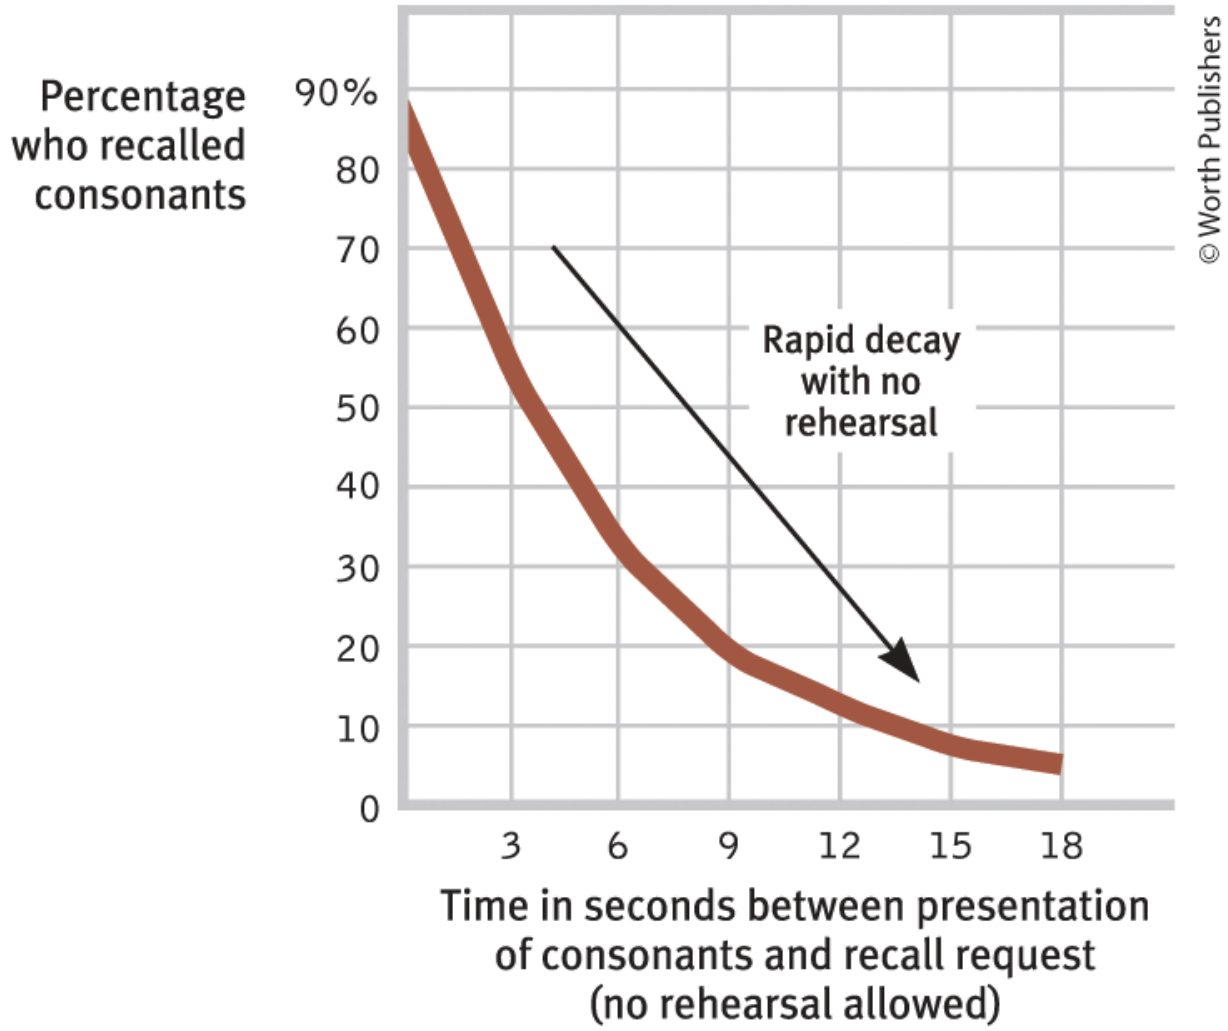
Extended description for FIGURE 24.3 Ebbinghaus' retention curve



The horizontal axis plots the number of repetitions of list on Day 1 and ranges from 8 to 64, in increments of 8. The vertical axis plots time in minutes taken to relearn list on day 2 and ranges from 0 to 20, in increments of 5. The curve begins from (8, 20); passes through

(16, 17.5), (24, 17), (32, 14.5), (42, 12), (53, 10); and ends at (64, 7.5). Text corresponding to the curve reads, As rehearsal increases, relearning time decreases. All data are approximate.

Return to FIGURE 24.3 Ebbinghaus' retention curve

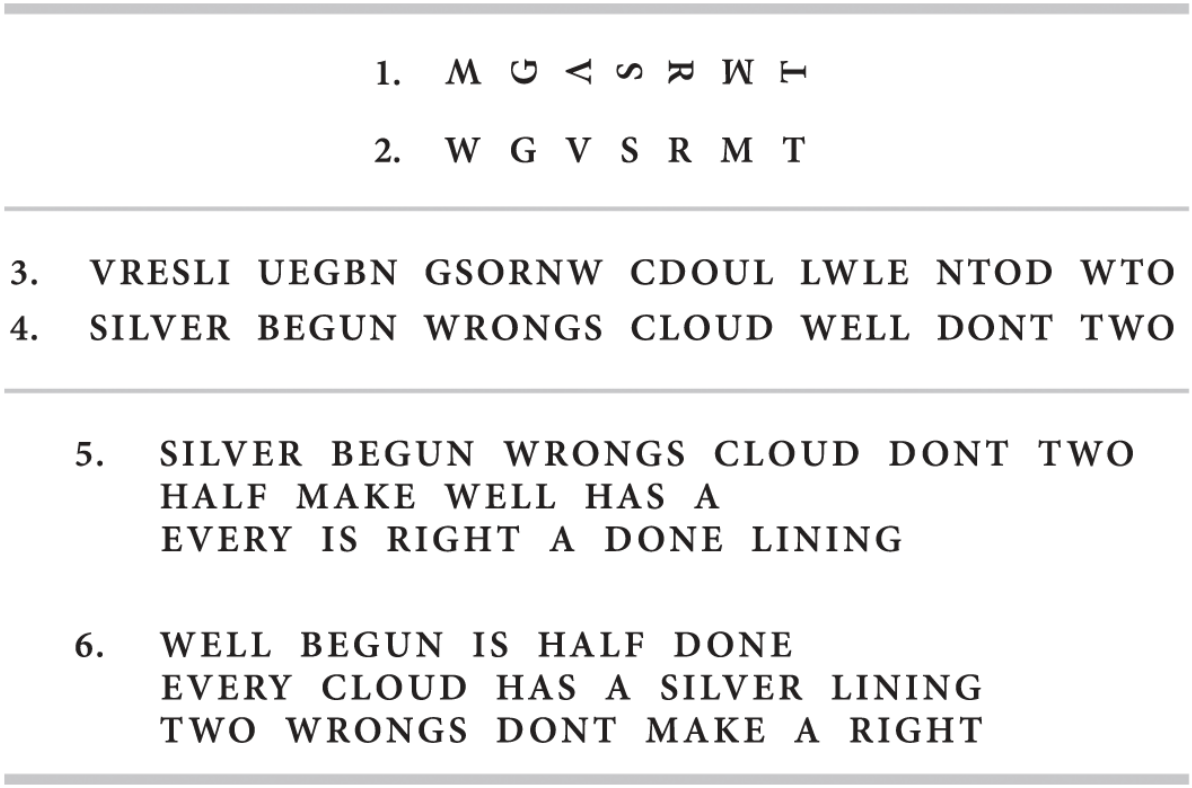


Extended description for FIGURE 24.4 A modified three-stage information-processing model of memory

Sensory input can be added to external events and stored in sensory memory. From sensory memory, the individual can pay attention to important or novel information and the memory is encoded. Once the memory is encoded in the working slash short-term memory, it can recycle back into working slash short-term memory through rehearsal and active maintenance. From working slash short-term memory encoding can move the memory in the long-term memory storage from where it can be retrieved later and available via the working slash short-term memory. Sensory memory through automatic processing gets stored in long-term memory storage.

Return to FIGURE 24.4 A modified three-stage information-processing model of memory

Extended description for FIGURE 24.6 Short-term memory decay

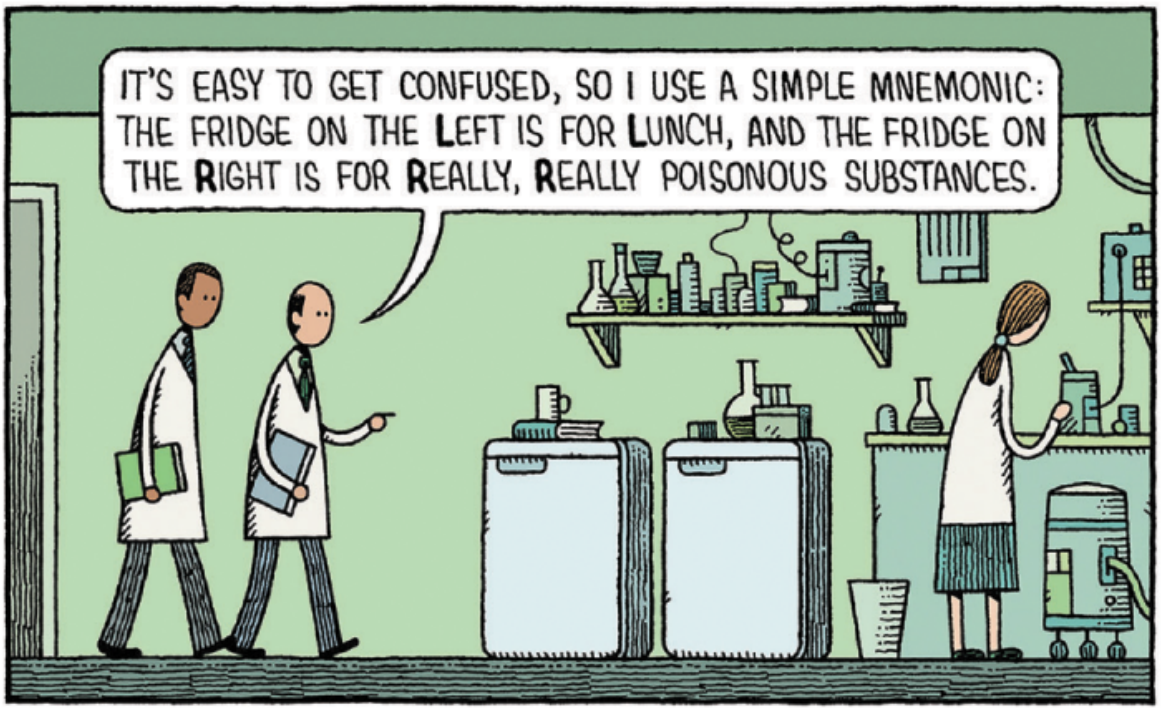


The horizontal axis represents time in seconds between presentation of consonants and recall request (no rehearsal allowed) and ranges from 0 to 18, in increments of 3. The vertical axis represents percentage who recalled consonants and ranges from 0

to 90 percent, in increments of 10. The curve begins from (0, 85) and passes through (6, 33) to end at (18, 5). A diagonal downward arrow corresponding to the curve reads, rapid decay with no rehearsal. All data are approximate.

Return to FIGURE 24.6 Short-term memory decay

Extended description for FIGURE 24.7 Chunking effects



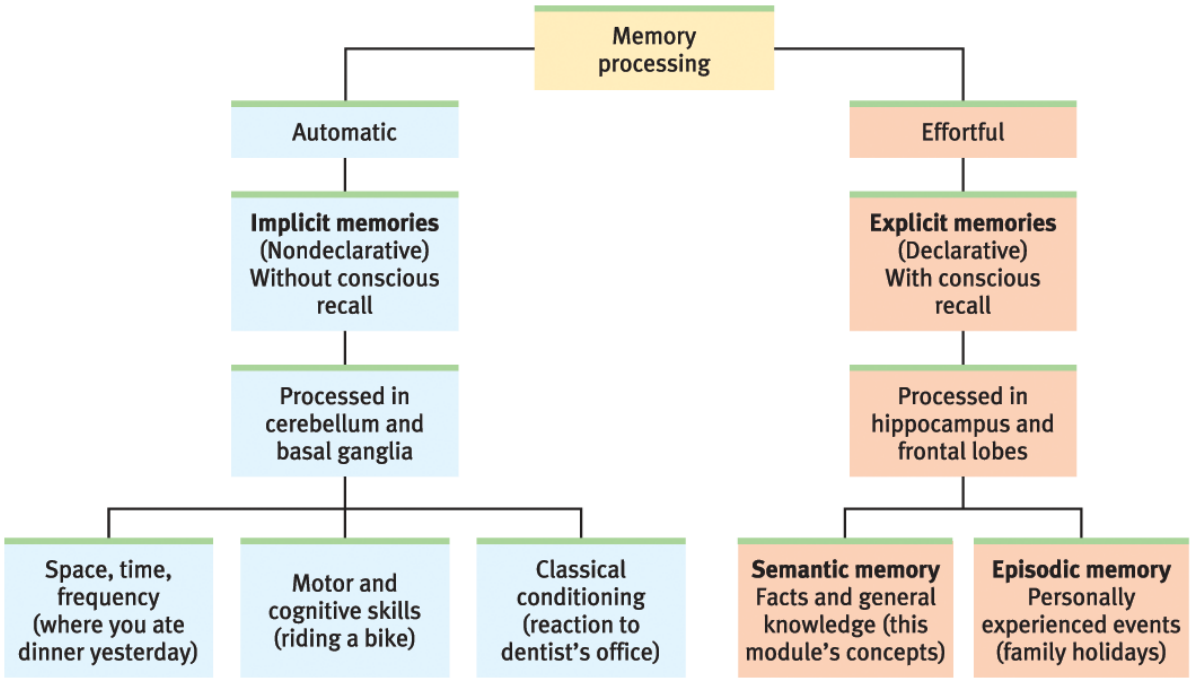
© Worth Publishers

The illustration shows three sets of examples. The first set shows two rows wherein row 1 has inverted-rotated copies of the letters in row 2 (W G V S R M T). The second set shows two rows wherein row 3 has scrambled copies of the words in Row 4 as follows: 3. VRESLI UEGBN GSORNW CDOUL LWLE NTOD WTO. 4. Silver Begun Wrongs Cloud Well Dont Two. The third set shows three sentences in each 5 and 6 with point 5 having jumbled words of sentences in point 6 as follows: 5. Top: Silver begun wrongs cloud dont two. Middle: Half

make well has a. Bottom: Every is right a done lining. 6. Top: Well begun is half done. Middle: Every cloud has a silver lining. Bottom: Two wrongs dont make a right.

Return to FIGURE 24.7 Chunking effects

Extended description for Mnemonics



Tom Gauld/Heart Agency

The first two scientists are having a conversation as they look at the side-by-side refrigerators. One says to the other, It's easy to get confused, so I use a simple mnemonic: The fridge on the left is for lunch, and the fridge on the right is for really, really poisonous substances.

Return to Mnemonics

Extended description for FIGURE 25.4 Our two memory systems

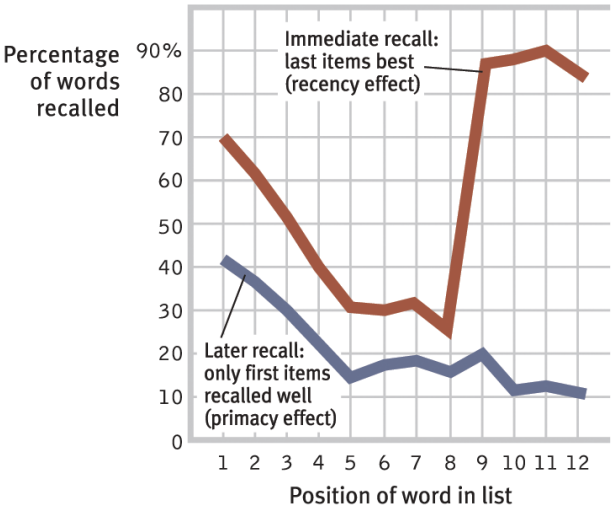
© Worth Publishers

Memory processing can be **automatic** or **effortful**. Memories processed automatically lead to **Implicit memories** (non-declarative): without conscious recall. Memories are then processed in cerebellum and basal ganglia. Memories processed this way are divided into three groups: Space, time, frequency (where you ate dinner yesterday); Motor and cognitive skills (riding a bike); and Classical conditioning (your reaction to a dentist's office). Memories processed effortfully lead to **Explicit memories** (declarative): with conscious recall. Memories are then processed in hippocampus and

frontal lobes. Memories processed this way are divided into two groups: **Semantic memory**, facts and general knowledge (this module's concept); and **episodic memory**, personally experienced events (family holidays).

Return to FIGURE 25.4 Our two memory systems

Extended description for FIGURE 25.6 The serial position effect



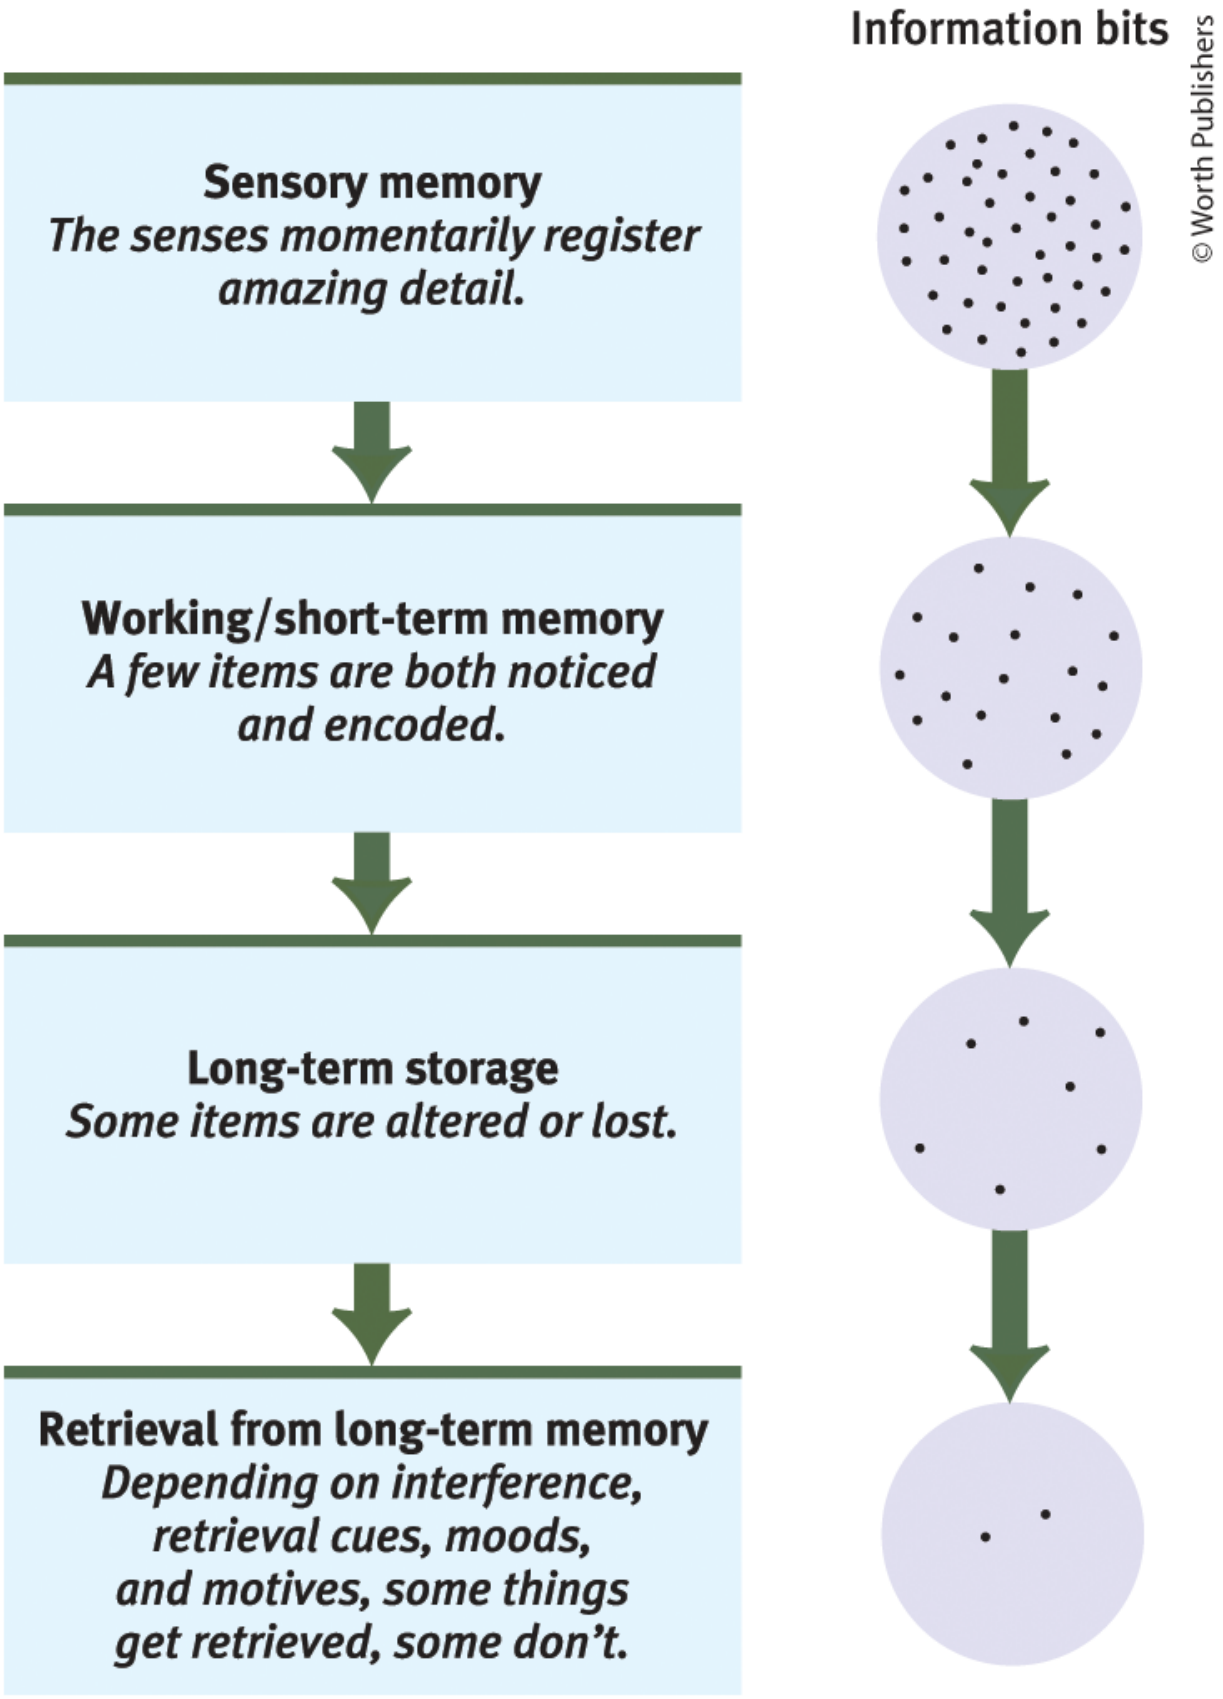


Photo: Kevork Djansezian/Getty Images
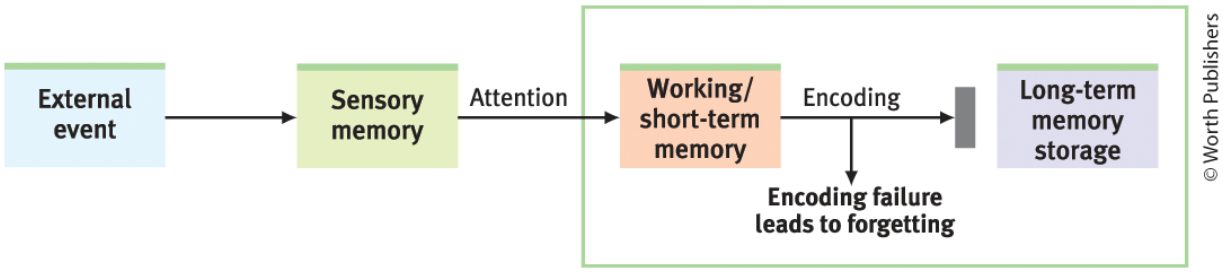
© Worth Publishers

In the graph, the horizontal axis represents the position of word in list and ranges from 0 to 12, in increments of 1. The vertical axis represents the percentage of words recalled and ranges from 0 to 90 percent, in increments of 10. A red curve begins at (1, 70), drops down to (5, 30), further declines to (8, 25), increases to (9, 88), slightly increases to (11, 90), and then slightly declines to end at (12, 84). The curve is labeled, Immediate recall: last items best (recency effect). A blue curve begins at (1, 42), drops down to (5, 15), and passes through a few ups and downs to end at (12, 11). The curve is labeled, Later recall: only first items recalled well (primacy effect). All data are approximate.

Return to FIGURE 25.6 The serial position effect

Extended description for FIGURE 26.1

When do we forget?



© Worth Publishers

The flowchart begins with **Sensory Memory:** *The senses momentarily register amazing detail.* A downward arrow points to the next box reading, **Working slash short-term memory:** *A few items are both noticed and encoded.* Another downward arrow points to the next box reading, **Long-term storage:** *Some items are altered or lost.* A final downward arrow point to the last box reading, **Retrieval from long-term memory:** *Depending on interference, retrieval cues, moods, and motives, some things get retrieved, some don't.*

The series of illustrations for Information Bits represents information as tiny dots inside four circles, each connected by downward arrows. The number of dots corresponds to the type of memory described in the flowchart to the left. The number of dots decreases from the top to the bottom.

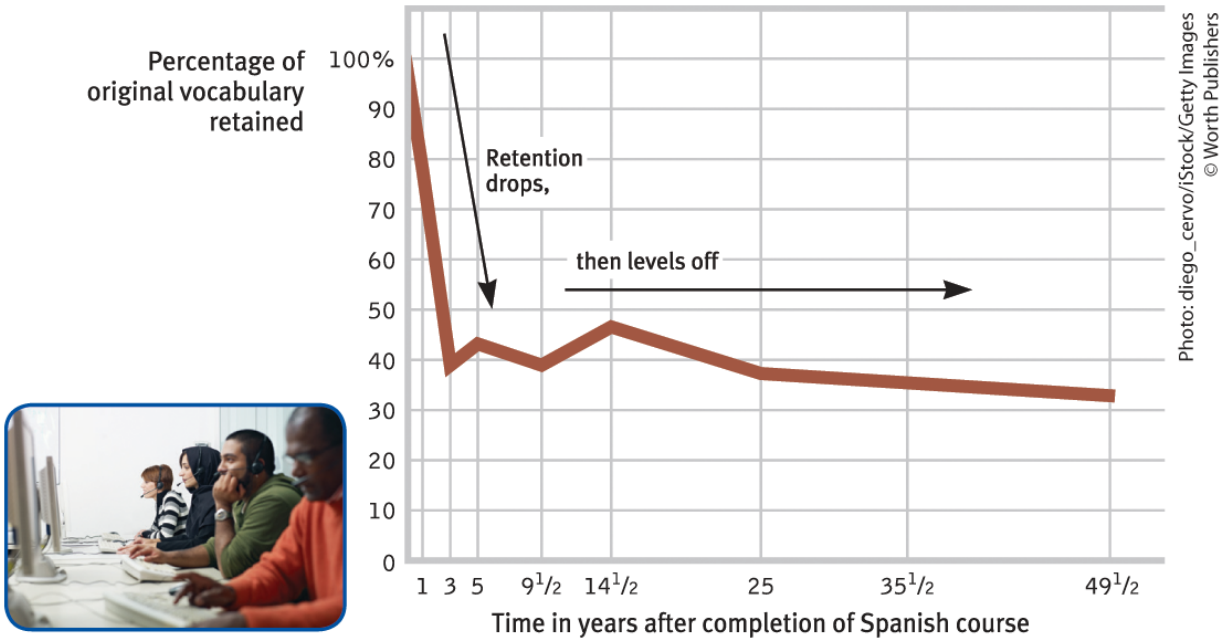
Return to FIGURE 26.1 When do we forget?

Extended description for FIGURE 26.2 Forgetting as encoding failure

External events are processed in the sensory memory. If they get attention, they proceed to the working slash short-term memory where encoding processes them into either long-term memory storage or encoding failure leads to forgetting. The flowchart from working slash short-term memory to long-term storage is enclosed in a box.

Return to FIGURE 26.2 Forgetting as encoding failure

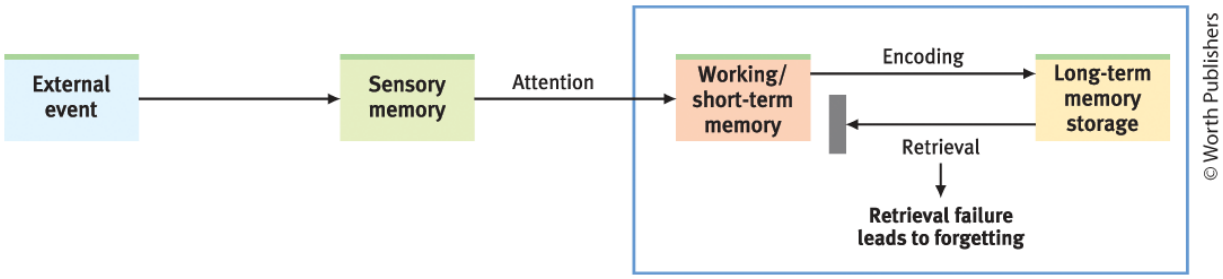
Extended description for Memory trees



Lightspring/Shutterstock

From left to right, there is a lush, green tree full of leaves; a tree with yellow leaves and some gaps where the back of the head would be; and a tree with red leaves and has much larger gaps with more leaves gone where the back of the head would be. Below the image a text reads, Memories start to fade. As the words move from left to right they become more transparent; that is, they fade away.

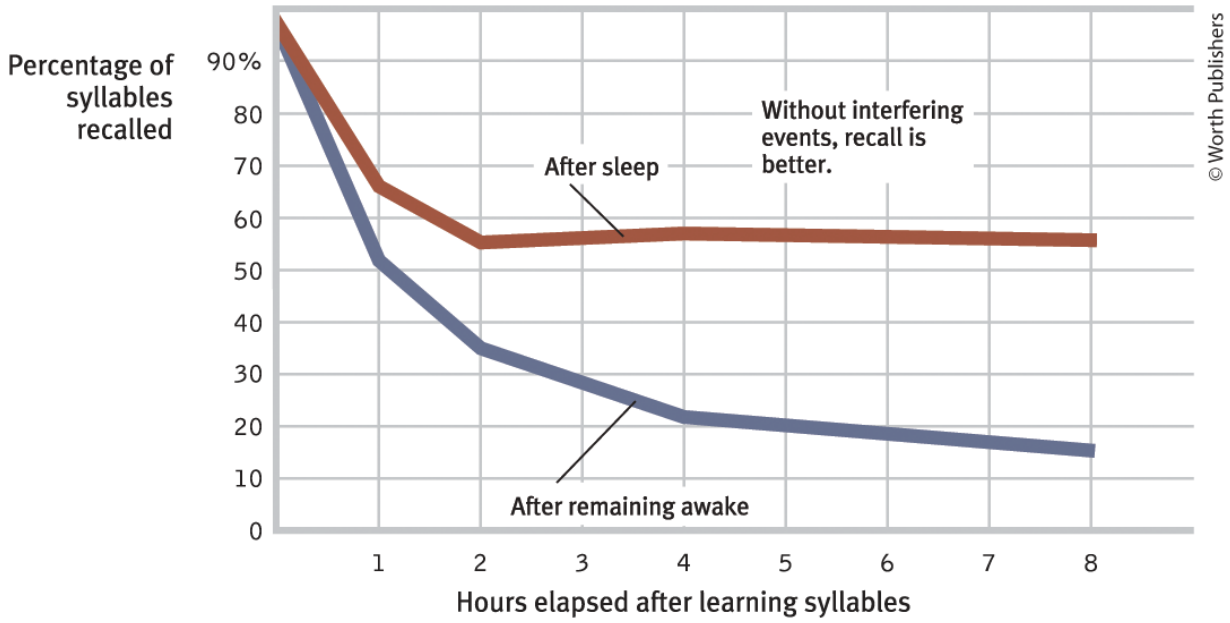
Return to Memory trees



Extended description for FIGURE 26.3 The forgetting curve for Spanish learned in school

The horizontal axis represents time in years after completion of a Spanish course and ranges from 1 to 49 and one-half. The vertical axis represents percentage of original vocabulary retained and ranges from 0 to 100 percent, in increments of 10. The curve starts from (0, 100); passes through (1, 80), (3, 39), (5, 44), (9 and one-half, 40), (14 and one-half, 48), (25, 38), (35 and one-half, 36); and ends at (49 and one-half, 32). The first 5 years of the curve show a downward arrow labeled retention drops. The rest of the curve shows a rightward arrow labeled, then levels off. All data are approximate.

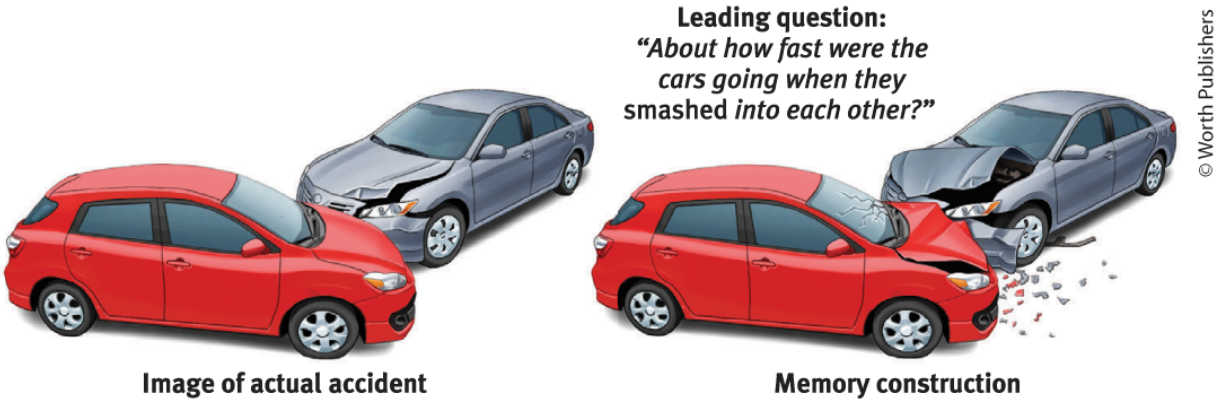
Return to FIGURE 26.3 The forgetting curve for Spanish learned in school



Extended description for FIGURE 26.4 Retrieval failure

External events are processed in the sensory memory. If they get attention, they proceed to the working slash short-term memory where encoding processes them into long-term memory storage. Memories can then be retrieved from the long-term memory storage and stored back in the work-short-term memory. Retrieval failure leads to forgetting. A box surrounds the flowchart from working slash short-term memory to long-term memory storage.

Return to FIGURE 26.4 Retrieval failure



Extended description for FIGURE 26.5 Retroactive interference

The horizontal axis represents hours elapsed after learning syllables and ranges from 0 to 8, in increments of 1. The vertical axis represents percentage of syllables recalled and ranges from 0 to 90 percent, in increments of 10. The curve for after sleep starts from (0, 100); passes through (1, 68) and (2, 55); and ends at (8, 56). The curve for after remaining awake starts from (0, 95); passes through (1, 52), (2, 35), and (4, 21); and ends at (8, 16). Text on the graph reads, Without interfering events, recall is better. All data are approximate.

Return to FIGURE 26.5 Retroactive interference

Extended description for FIGURE 26.6 Memory construction

The first part of the illustration is labeled, Image of actual accident, and shows car 1 hitting the driver-side headlight of car 2. The visible damage to car 1 is minor, and there is no visible damage to car 2. A text above the second part of the illustration reads, Leading question: *"About how fast were the cars going when they smashed into each other?"* The second part is labeled, Memory construction, and shows car 1 hitting the driver-side headlight of car 2 and the damage to car 1 and car 2 is substantially greater than in the first image. Broken glass pieces are present at the accident site.

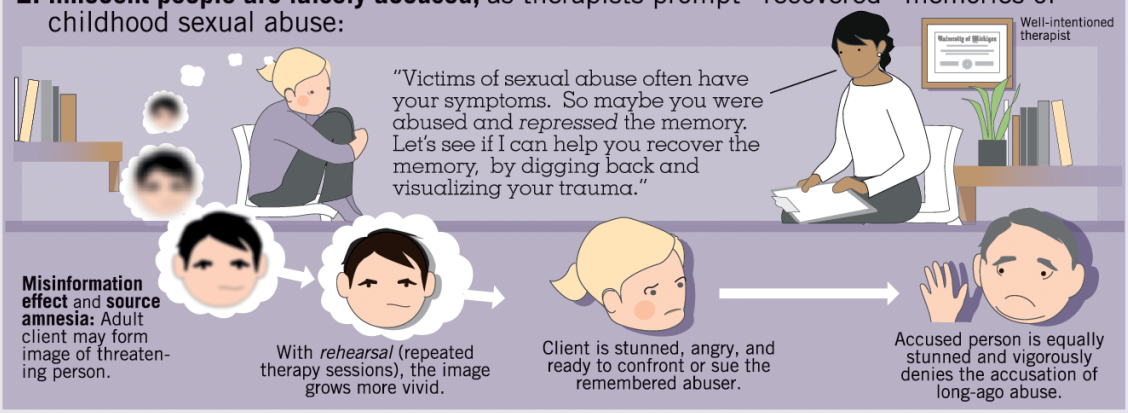
Extended description for Discerning true

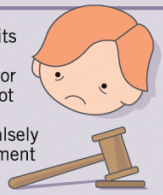
and false memories

Thinking Critically About:



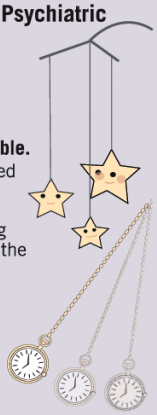
Can Memories of Childhood Sexual Abuse Be Repressed and Then Recovered?

© Worth Publishers



Two Possible Tragedies:

1. People doubt childhood sexual abuse survivors who tell their secret.



2. Innocent people are falsely accused, as therapists prompt "recovered" memories of childhood sexual abuse:

Professional organizations (including the American Medical, American Psychological, and American Psychiatric Associations) are working to find sensible common ground to resolve psychology's "memory war":[1]

- **Childhood sexual abuse happens** and can leave its victims at risk for problems ranging from sexual dysfunction to depression.[2] But there is no "survivor syndrome"—no group of symptoms that lets us spot victims of sexual abuse.[3]
- **Injustice happens.** Innocent people have been falsely convicted. And guilty people have avoided punishment by casting doubt on their truth-telling accusers.
- **Forgetting happens.** Children abused when very young may not have understood the meaning of their experience or remember it. Forgetting long-ago good and bad events is an ordinary part of everyday life.
- **Recovered memories are common.** Cued by a remark or an experience, we may recover pleasant or unpleasant memories of long-forgotten events. But does the unconscious mind forcibly repress painful experiences, and can these experiences be recovered by therapist-aided techniques?[4] Memories that surface naturally are more likely to be true.[5]
- **Memories of events before age 4 are unreliable.** Infantile amnesia results from not yet developed brain pathways. Most psychologists therefore doubt "recovered" memories of abuse during infancy.[6] The older a child was when suffering sexual abuse, and the more severe the abuse, the more likely it is to be remembered.[7]
- **Memories "recovered" under hypnosis are especially unreliable.**
- **Memories, whether real or false, can be emotionally upsetting.** What was born of mere suggestion can become, like an actual event, a stinging memory that drives bodily stress.[8]

Psychologists question whether *repression* ever occurs.
(See the Psychological Disorders modules for more on this concept, which is central to Freud's theory.)

Traumatic experiences (witnessing a loved one's murder, being terrorized by a hijacker or rapist, losing everything in a natural disaster) → **TYPICALLY LEAD TO** → **vivid, persistent, haunting memories**[9]

The Royal College of Psychiatrists Working Group on Reported Recovered Memories of Child Sexual Abuse advised that "when memories are 'recovered' after long periods of amnesia, particularly when extraordinary means were used to secure the recovery of memory, there is a high probability that the memories are false." [10]

1. Patihis et al., 2014. 2. Freyd et al., 2007. 3. Kendall-Tackett et al., 1993. 4. McNally & Geraerts, 2009. 5. Geraerts et al., 2007. 6. Gore-Felton et al., 2000; Knapp & VandeCreek, 2000. 7. Goodman et al., 2003. 8. McNally, 2003, 2007. 9. Porter & Peace, 2007; Goldfarb et al., 2019. 10. Brandon et al., 1998.

Introductory text reads, Why have reports of repressed and recovered memories been so hotly debated?

The infographic is divided into three panels as follows:

The first panel is headed, **Two Possible Tragedies. 1. People doubt childhood sexual abuse survivors who tell** their **secret. 2. Innocent people are falsely accused**, as therapists prompt "recovered" memories of childhood sexual abuse:

An illustration shows a client sitting on a chair with her knees drawn up under her chin. A well-intentioned therapist sits opposite to her with a clipboard on her lap and looks at the client. The therapist says, "Victims of sexual abuse often have your symptoms. So maybe you were abused and *repressed* the memory. Let's see if I can help you recover the memory, by digging back and visualizing your trauma." A series of thought bubbles arise from the client's head. The first thought bubble shows a blurred image of a man. Corresponding text reads, **Misinformation effect** and **source amnesia**: Adult client may form image of threatening person. Next thought bubble shows a clearer image of the man. Corresponding text reads, With *rehearsal* (repeated therapy sessions), the image grows more vivid. An arrow points to an image of a dismayed client's face. Corresponding text reads, Client is stunned, angry, and ready to confront or sue the remembered abuser. Another arrow points to a clear image of a man looking very sad, with his hand up.

Corresponding text reads, Accused person is equally stunned and vigorously denies the accusation of long-ago abuse.

The second panel shows the text: **Professional organizations (including the** American **Medical,** American **Psychological, and** American **Psychiatric Associations) are working to find sensible common ground to resolve psychology's "memory war:"** (Patihis et al., 2014 a). A bulleted list below reads as follows:

Bullet point 1: **Childhood sexual abuse happens** and can leave its victims at risk for problems ranging from sexual dysfunction to depression (Freyd et al., 2007). But there is no "survivor syndrome" — no group of symptoms that lets us spot victims of sexual abuse (Kendall-Tackett et al., 19 93).

Bullet point 2: **Injustice happens.** Innocent people have been falsely convicted. And guilty people have avoided punishment by casting doubt on their truth-telling accusers.

Bullet point 3: **Forgetting happens.** Children abused when very young may not have understood the meaning of their experience or remember it. Forgetting long-ago good and bad events is an ordinary part of everyday life.

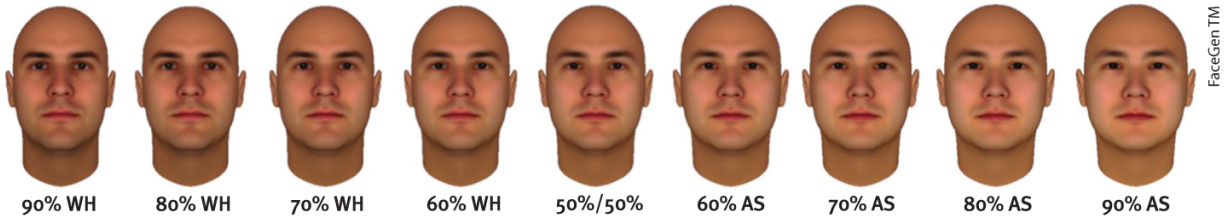
Bullet point 4: **Recovered memories are common.** Cued by a remark or an experience, we may recover pleasant or unpleasant memories of long-forgotten events. But does the unconscious mind

forcibly repress painful experiences, and can these experiences be recovered by therapist-aided techniques? (McNally and Geraerts, 2009). Memories that surface naturally are more likely to be true (Geraerts et al., 2007).

Bullet point 5: **Memories of events before age 4 are unreliable.** Infantile amnesia results from not yet developed brain pathways. Most psychologists therefore doubt "recovered" memories of abuse during infancy (Gore-Felton et al., 2000; Knapp and VandeCreek, 2000). The older a child was when suffering sexual abuse, and the more severe the abuse, the more likely it is to be remembered (Goodman et al., 2003).

Bullet point 6: **Memories "recovered" under hypnosis are especially unreliable.**

Bullet point 7: **Memories, whether real or false, can be emotionally upsetting.** What was born of mere suggestion can become, like an actual event, a stinging memory that drives bodily stress (McNally, 2003, 2007).



The third panel is divided into three sections. Text in the first section reads, **Psychologists question whether *repression* ever occurs.** (See the Psychological Disorders modules for more on this more on this concept, which is central to Freud's theory.)

Text in the second section reads, **Traumatic experiences** (witnessing a loved one's murder, being terrorized by a hijacker or rapist, losing everything in a natural disaster) typically lead to vivid, persistent, haunting memories. (Porter and Peace, 2007; Goldfarb et al., 2019).

Text in the third section reads, **The Royal College of Psychiatrists Working Group on Reported Recovered Memories of Child Sexual Abuse** advised that “when memories are 'recovered' after long periods of amnesia, particularly when extraordinary means were used to secure the recovery of memory, there is a high probability that the memories are false” (Brandon et al, 19 98).

Extended description for FIGURE 27.1 Categorizing faces influences recollection

From left to right, the labels read as follows: 90 percent White, 80 percent White, 70 percent White, 60 percent White, 50 percent slash 50 percent, 60 percent Asian, 70 percent Asian, 80 percent Asian, and 90 percent Asian.

Return to FIGURE 27.1 Categorizing faces influences recollection

Extended description for Fear factor

© Worth Publishers

The infographic is divided into three panels as follows:

The top panel shows the text, Many people fear flying more than driving. **HOWEVER:** Per mile traveled, people in the U.S. are 500 times more likely to die in a vehicle accident than on a scheduled flight. (National Safety Council, 2021; National Highway Traffic Safety Administration, 2021). An illustration shows a timeline starting with the year 2002 at the far left and the year 2019 three-quarters of the way across. Three illustrations accompany the timeline: an airplane flying toward one of the World Trade Center buildings toward the far left; an ambulance with an illuminated light bar toward the middle; and an upside-down car with fluids leaking out onto the ground toward the far right.

Arrows lead from circled 2002 and 2019 on the timeline to the middle panel where the text on the left reads, From 2002 to 2019, for example, **484,100** people died in U.S. car, light truck, heavy truck, and bus accidents, and **154** died on scheduled U.S. airline flights. In the same panel, toward the right, a graph shows the number of U.S. traffic deaths. Text on the left of the graph reads, In the three months after 9 slash 11, **FEAR OF FLYING** led more Americans to travel by car, and some to die: (Gaissmater and Gigerenzer, 2012; Gigerenzer, 2004, 2006). The graph's vertical axis is labeled Number of U.S. traffic deaths and ranges from 2200 to 3600, in increments of 200. The horizontal axis lists each month of the year starting with January and ending in December. A curve for Number of traffic deaths, 2001, starts from (January, 2650), increases in a jagged pattern, and ends at (December, 3350). A curve for Average number of traffic deaths, 19 96 to 2000, starts from (January, 2750), follows a

similar jagged pattern as the previous curve, and ends at (December, 3200). A circle enclosing both curves from October to December is labeled, October to December 2001: 353 excess deaths. All data are approximate. A text on the right of the graph reads, In the year following 9 slash 11, these researchers estimated, 1500 Americans had "lost their lives on the road by trying to avoid the risk of flying."

The bottom panel is titled, **WHY DO WE FEAR THE WRONG THINGS?** The left half shows four points as follows:

1. We fear what our ancestral history has prepared us to fear: Snakes, lizards, and spiders combined now kill a tiny fraction of the number killed by modern-day threats, such as cars and cigarettes. Ancestral risks also prepare us to fear confinement and heights, and therefore flying. Three illustrations show a boy peering through his fingers at a spider; a snake; and two people sitting on an airplane.

2. We fear what we cannot control: Driving we control; flying we do not. Two illustrations show hands on a car steering wheel and an airplane.

3. We fear what is immediate: Dangers of flying are mostly in the moments of takeoff and landing. Dangers of driving are spread across many moments, each trivially dangerous.

4. Thanks to the availability heuristic, we fear what is most readily available in memory: Vivid images of horrific airline crashes feed

our judgments of risk. People may fear sharks more than cigarettes or the effects of an unhealthy diet. (Daley, 2011). An illustration titled, **"Vivid Image!"** shows a shark biting the leg of a swimmer, with a visible cloud of red blood. Accompanying text reads, Shark attacks kill about one American per year. Another illustration titled, **"Harder to visualize,"** shows a heart with a shadow around it. Accompanying text reads, Heart disease kills 800,000 Americans per year.

The right half of the bottom panel shows the text, We remember and fear **disasters** (terrorism, hurricanes, earthquakes) that kill people dramatically, in bunches. A text in a box reads, We fear too little the **less dramatic and ongoing threats** that claim lives one by one: Bullet point 1: Each year, guns kill nearly 40,000 Americans — in homicides, suicides, and accidents. (U S A Facts, 2021). Yet renewed calls for U.S. gun control tend to follow the well-publicized, mass shootings. An illustration shows a child reaching for a gun on a shelf. Bullet point 2: Worldwide, 500,000 children die each year from diarrhea, with tragically little notice. An illustration shows a woman holding a baby.

A text at the bottom of the right half reads, "If it’s in the news, don’t worry about it. The very definition of news is ’something that hardly ever happens.’" (Schneider, 2007).

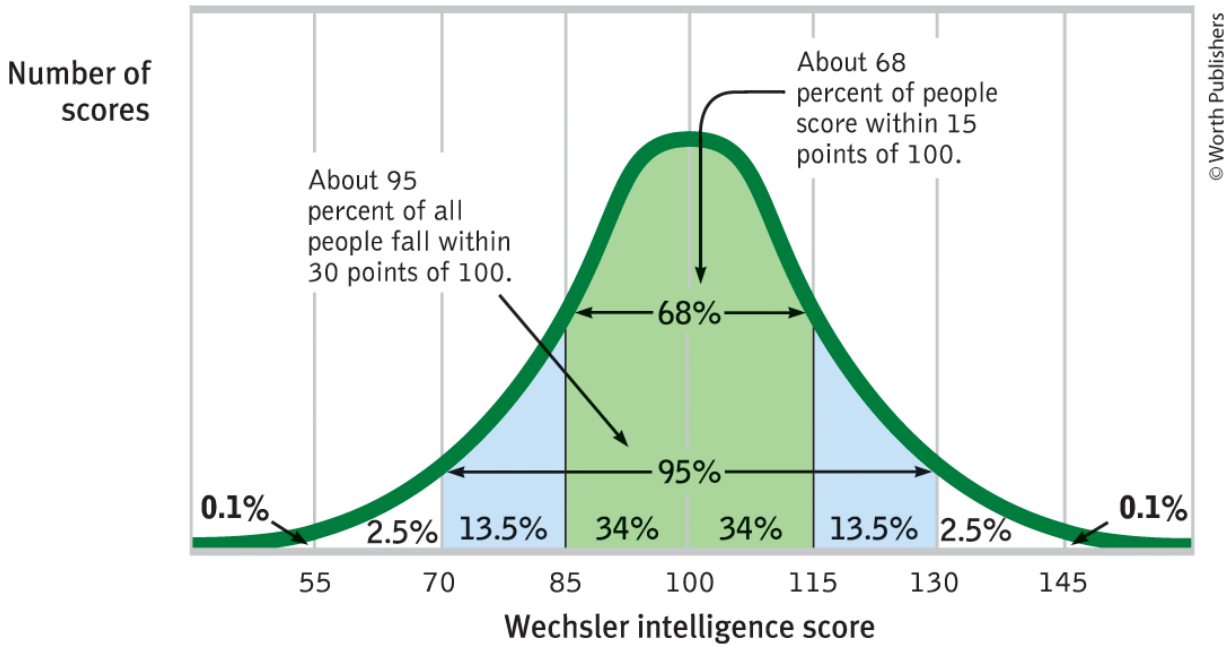
Extended description for Innate intelligence

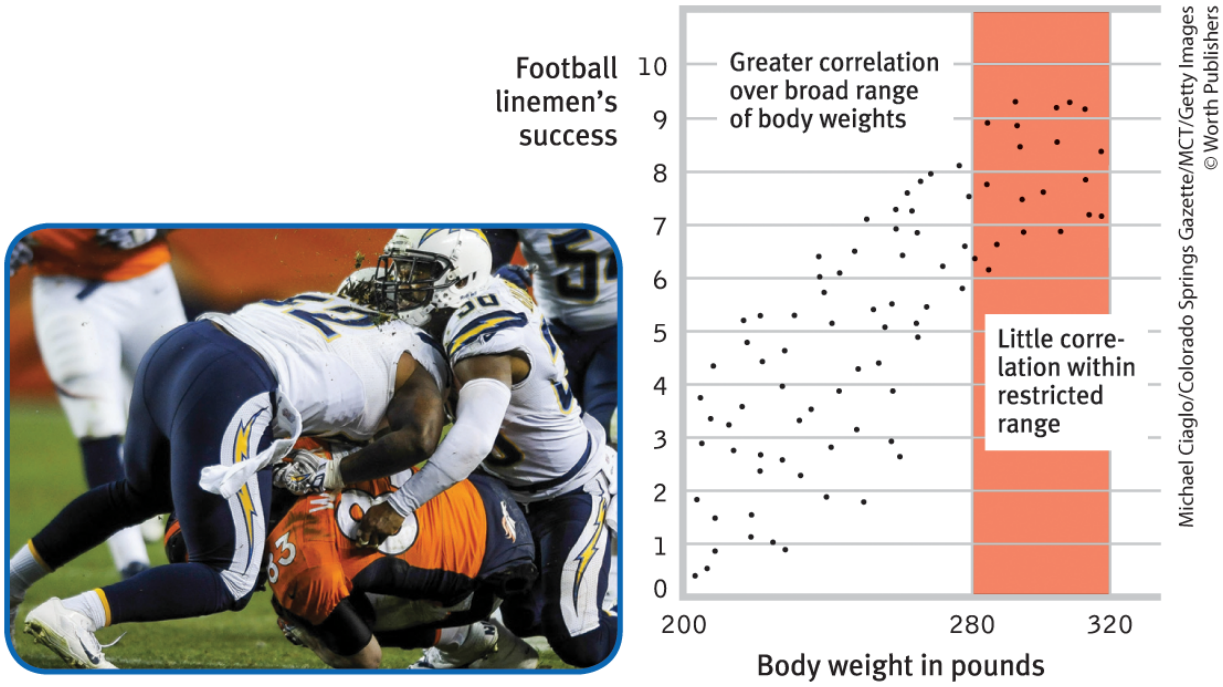


© Dave Coverly/speedbump.com

One of the woman says, “That’s my boy, Mark. He’s 39, but he’s already reading at a 42-year-old level.” Text below the cartoon reads, Mrs. Randolph takes mother’s pride too far.

Return to Innate intelligence

Extended description for FIGURE 30.2 The normal curve

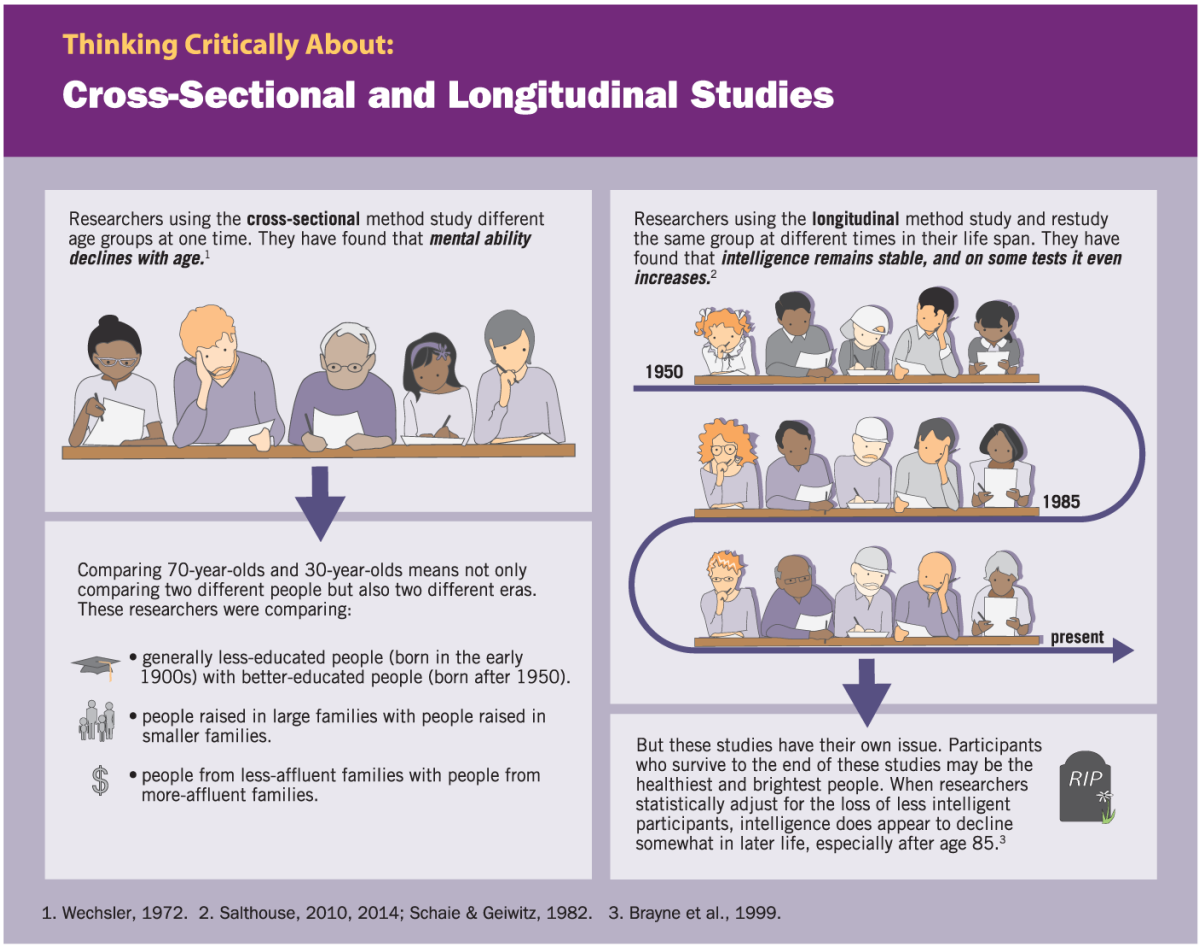


The graph shows a bell-shaped curve with different areas indicated with colors and percentages. The horizontal axis depicts the Wechsler intelligence score and ranges from 40 to 160, in increments of 15. The vertical axis represents the number of scores. The percentages of people who fall within different score ranges are presented as follows: Below 55, 0.1 percent; 55 to 70, 2.5 percent; 70 to 85, 13.5 percent; 85 to 100, 34 percent; 100 to 115, 34 percent; 115 to 130, 13.5 percent; 130 to 145, 2.5 percent; and Above 145, 0.1 percent. Text pointing to the area under the curve from 85 to 115 (68 percent) reads, About 68 percent of people score within 15 points of

100. A text pointing to the area under the curve from 70 to 130 (95 percent) reads, About 95 percent of all people fall within 30 points of 100.

Return to FIGURE 30.2 The normal curve

Extended description for FIGURE 30.3 Diminishing predictive power



The photo shows an American football player duck under the tackle of two other American football players.

The scatterplot shows football linemen's success against body weight. The horizontal axis represents body weight in pounds and ranges from 200 to 320. A vertical region from 280 to 320 is shaded. The vertical axis represents football linemen's success and ranges from 0 to 10, in increments of 1. The data points are distributed randomly from (200, 0) and (200, 4) to (320, 7) and (320, 9). The

region between 200 and 280 is labeled, Greater correlation over broad range of body weights; and the region between 280 and 320 is labeled, Little correlation within restricted range. All data are approximate.

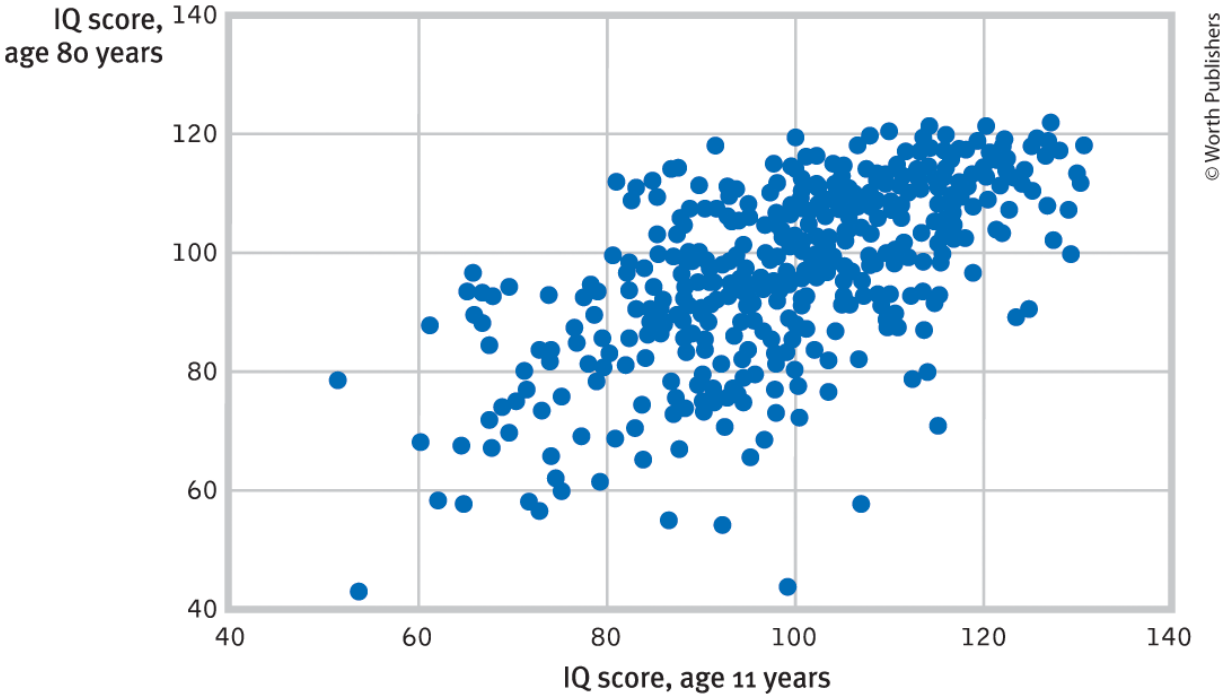
Return to FIGURE 30.3 Diminishing predictive power

Extended description for Cross-sectional and longitudinal studies

© Worth Publishers

The infographic is divided into two halves with both halves showing two sections as follows.

Text in the top section of the left half reads, Researchers using the **cross-sectional** method study different age groups at one time. They

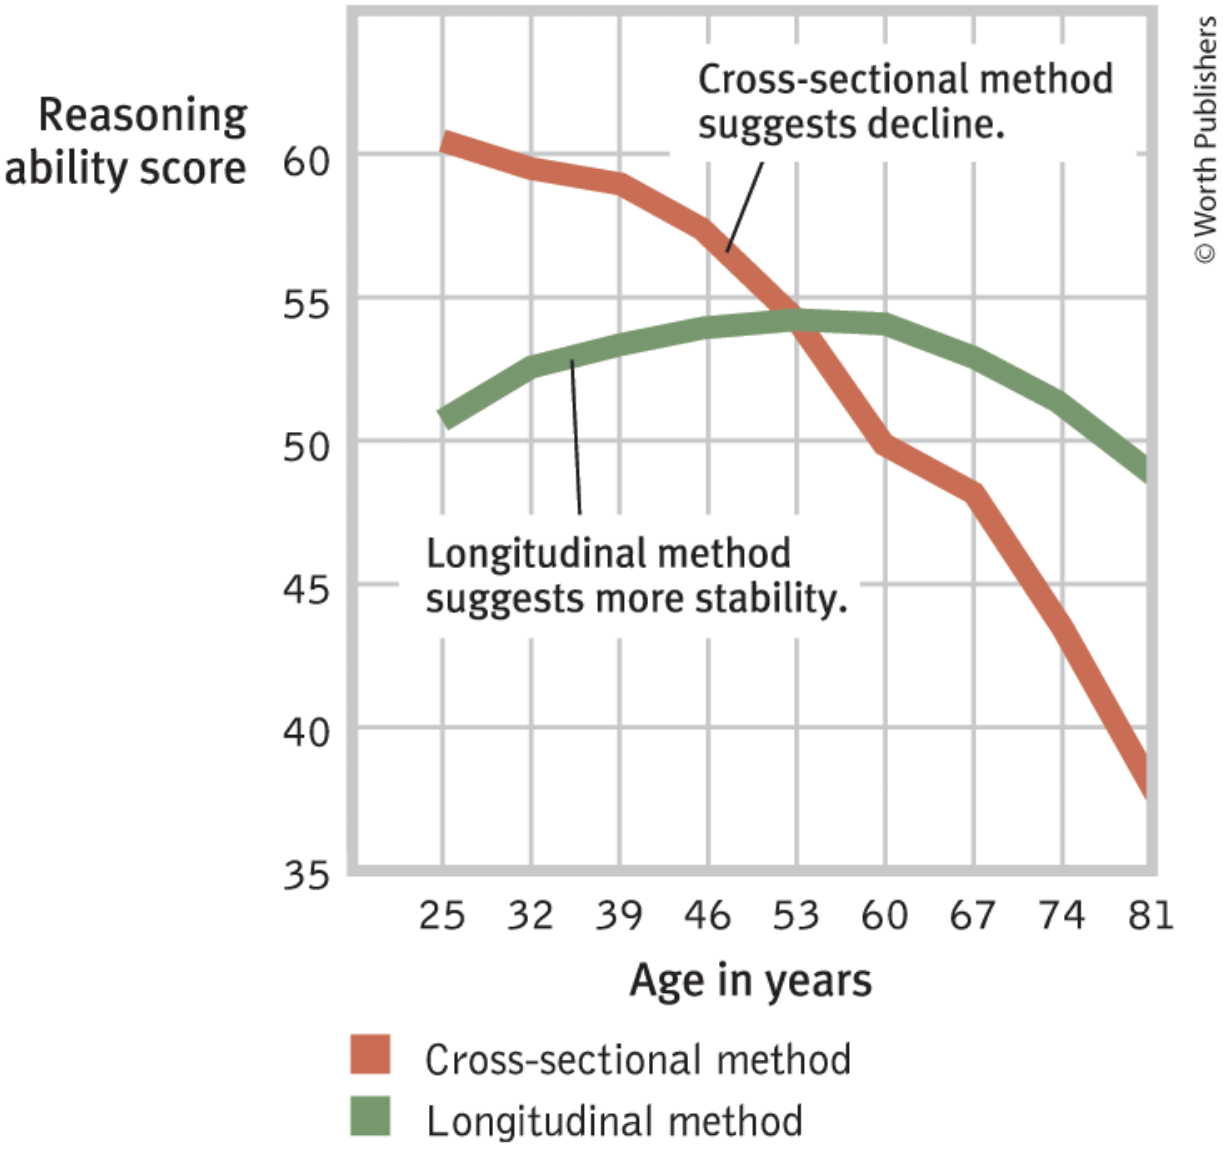


have found that ***mental ability declines with age*** (Wechsler, 19 72). An illustration shows five people of different age groups taking up a written test. An arrow points down to the lower section. Text reads, Comparing 70-year-olds and 30-year-olds means not only comparing two different people but also two different eras. These researchers were comparing: Bullet point 1: Generally less-educated people (born in the early 1900s) with better-educated people (born after 19 50). An illustration shows a gradation cap. Bullet point 2: People raised in large families with people raised in smaller families. An illustration shows four family members, two adults and two children. Bullet point 3: People from less-affluent families with people from more-affluent families. An illustration shows a dollar sign.

Text in the top section of the right half reads, Researchers using the **longitudinal** method study and restudy the same group at different times in their life span. They have found that ***intelligence remains stable, and on some tests it even increases*** (Salthouse, 2010, 2014; Schaie and Geiwitz, 19 82). An illustration shows a timeline with people of different age groups taking a written test in 19 50, then 19 85, and then at present. An arrow points down to the lower section. A text reads, But these studies have their own issue. Participants who survive to the end of these studies may be the healthiest and brightest people. When researchers statistically adjust for the loss of less intelligent participants, intelligence does appear to decline somewhat in later life, especially after age 85 (Brayne et al, 19 99).

An illustration shows a tombstone with a flower. Text on the tombstone reads, R I P.

Return to Cross-sectional and longitudinal studies

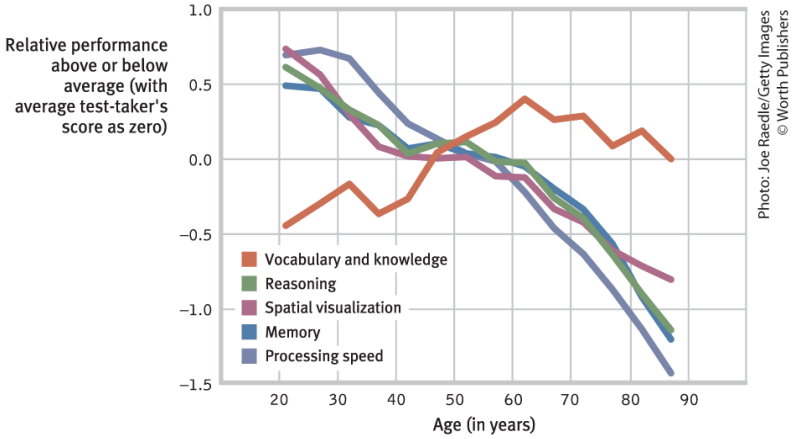


Extended description for FIGURE 30.4 Intelligence endures

The horizontal axis represents I Q score, age 11 years, and ranges from 40 to 140, in increments of 20. The vertical axis represents I Q score, age 80 years, and ranges from 40 to 140, in increments of 20. The data points are present between 60 and 130 on the horizontal axis and 55 and 121 on the vertical axis with the majority of data points lying between 90 and 120 on the horizontal axis and 70 and 120 on the vertical axis. All data are approximate.

Return to FIGURE 30.4 Intelligence endures

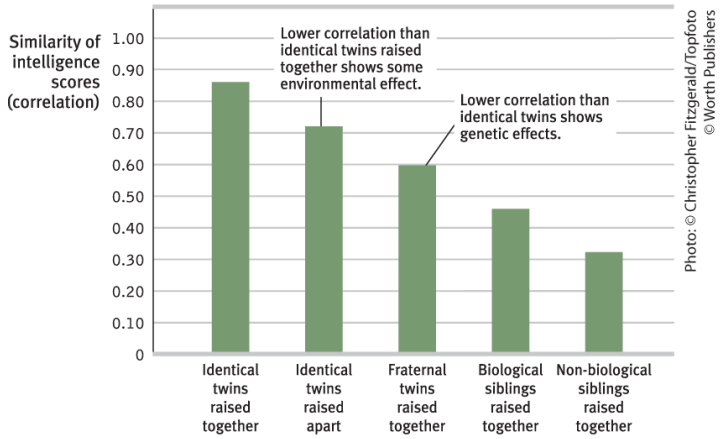
Extended description for FIGURE 30.5 Cross-sectional versus longitudinal testing of intelligence at various ages



The horizontal axis represents age in years and ranges from 18 to 81, in increments of 7. The vertical axis represents the reasoning ability score and ranges from 35 to 60, in increments of 5. The cross-sectional method curve starts at (25, 61); passes through (32, 59.5), (39, 59), (46, 57), (53, 54), (60, 50), (67, 48), and (74, 44); and ends at (81, 38). A corresponding text reads, cross-sectional method suggests decline. The longitudinal method curve starts at (25, 51); passes through (32, 52.5), (39, 53), (46, 54), (53, 54.5), (60, 54), (67, 53), and (74, 52); and ends at (81, 49). A corresponding text reads, longitudinal method suggests more stability. All data are approximate.

Return to FIGURE 30.5 Cross-sectional versus longitudinal testing of intelligence at various ages

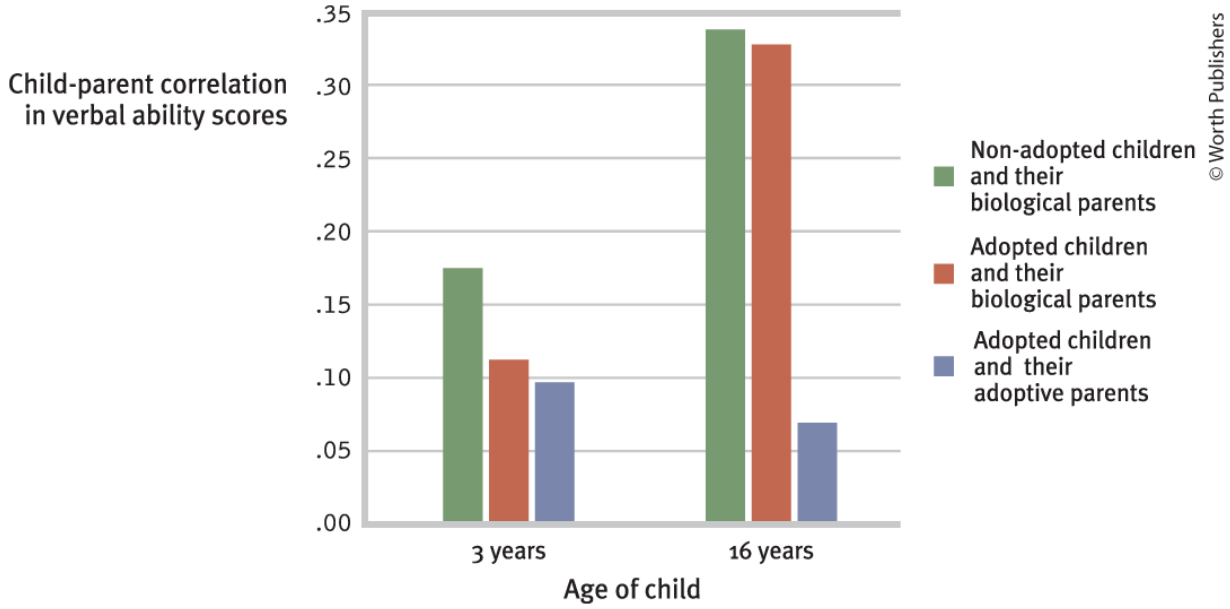
Extended description for FIGURE 30.6 With age, we lose and we win



In the graph, the horizontal axis is labeled age (in years) and ranges from 10 to 90, in increments of 10. The vertical axis is labeled relative performance above or below average (with average test-taker's score as zero) and ranges from negative 1.5 to 1.0, in increments of 0.5. The curve denoting vocabulary and knowledge is a positively sloped, non-linear curve starting at (21, negative 0.45) and ending at (87, 0.0). The curves denoting reasoning, spatial visualization, memory, and processing speed are negatively sloped, non-linear curves starting at points between 0.5 to 0.75 on the vertical axis and 20 on the horizontal axis and ending at points between negative 1.4 to negative 0.75 on the vertical axis and 86 on the horizontal axis. These four curves are all very similar in their trajectories. All data are approximate.

Return to FIGURE 30.6 With age, we lose and we win

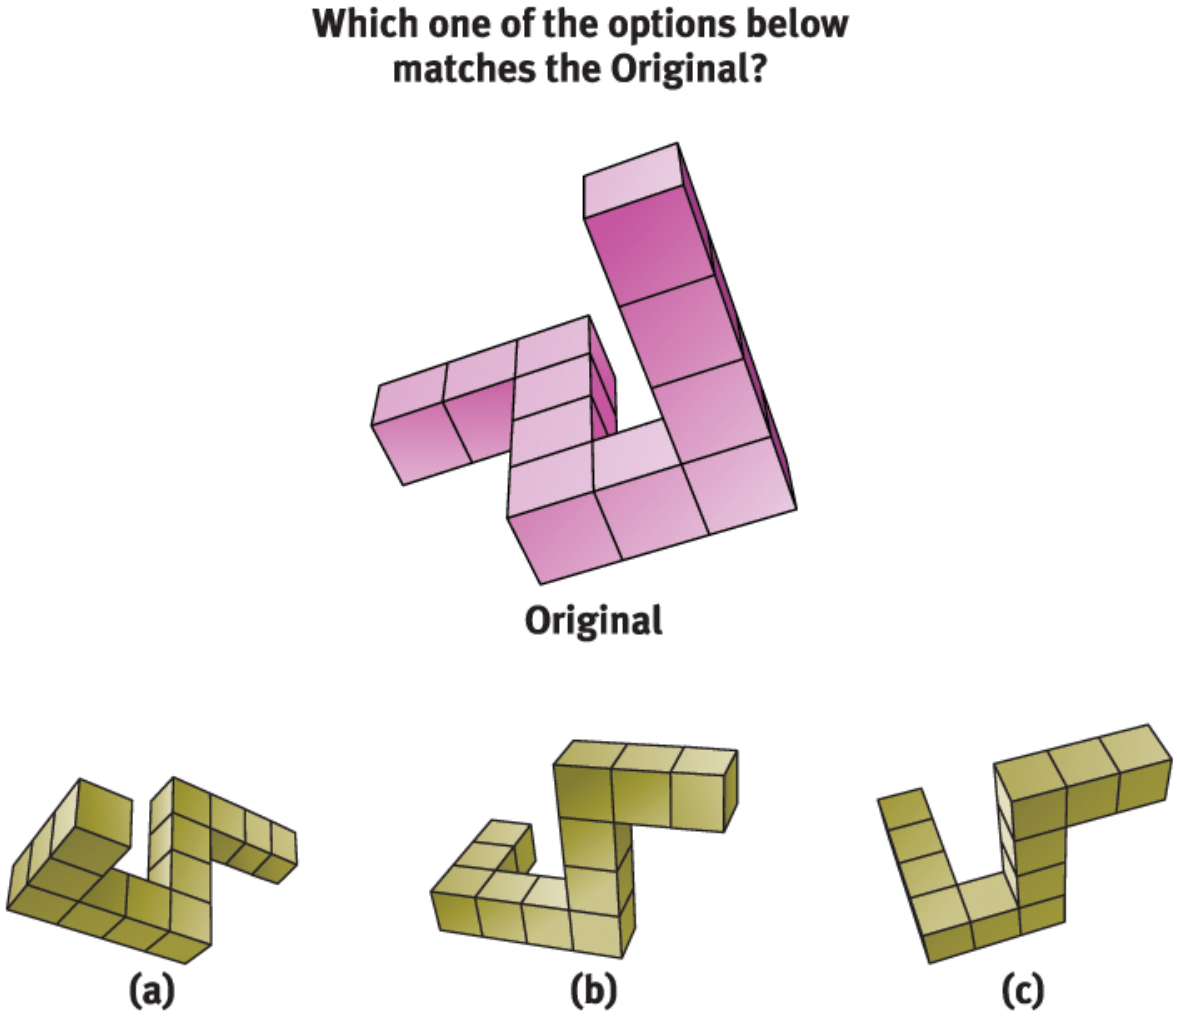
Extended description for FIGURE 31.1 Intelligence: Nature and nurture



In the graph, the horizontal axis shows five bars for five different types of twins. The vertical axis is labeled similarity of intelligence scores (correlation) and has values from 0 to 1.00, in increments of 0.10. The data are as follows: Identical twins raised together, 0.85; Identical twins raised apart, 0.71; Fraternal twins raised together, 0.60; Biological siblings raised together, 0.46; and Non-biological siblings raised together, 0.32. All data are approximate. The bar for identical twins raised apart is labeled, Lower correlation than identical twins raised together shows some environmental effect. The bar for fraternal twins raised together is labeled, Lower correlation than identical twins shows genetic effects.

Return to FIGURE 31.1 Intelligence: Nature and nurture

Extended description for FIGURE 31.2 In verbal ability, who do adopted children resemble?



The horizontal axis represents age of child and is labeled 3 years and 16 years. The vertical axis represents child-parent correlation in verbal ability scores and ranges from .00 to .35, in increments of .05. The data for the 3-year-old children are: Non-adopted children and their biological parents, 0.17; Adopted children and their biological parents, 0.11; and Adopted children and their adoptive parents, 0.095. The data for the 16-year-old children are: Non-adopted children and their biological parents, 0.34; Adopted children and

their biological parents, 0.33; and Adopted children and their adoptive parents, 0.07. All data are approximate.

Return to FIGURE 31.2 In verbal ability, who do adopted children resemble?

Extended description for FIGURE 31.3 A mental rotation test

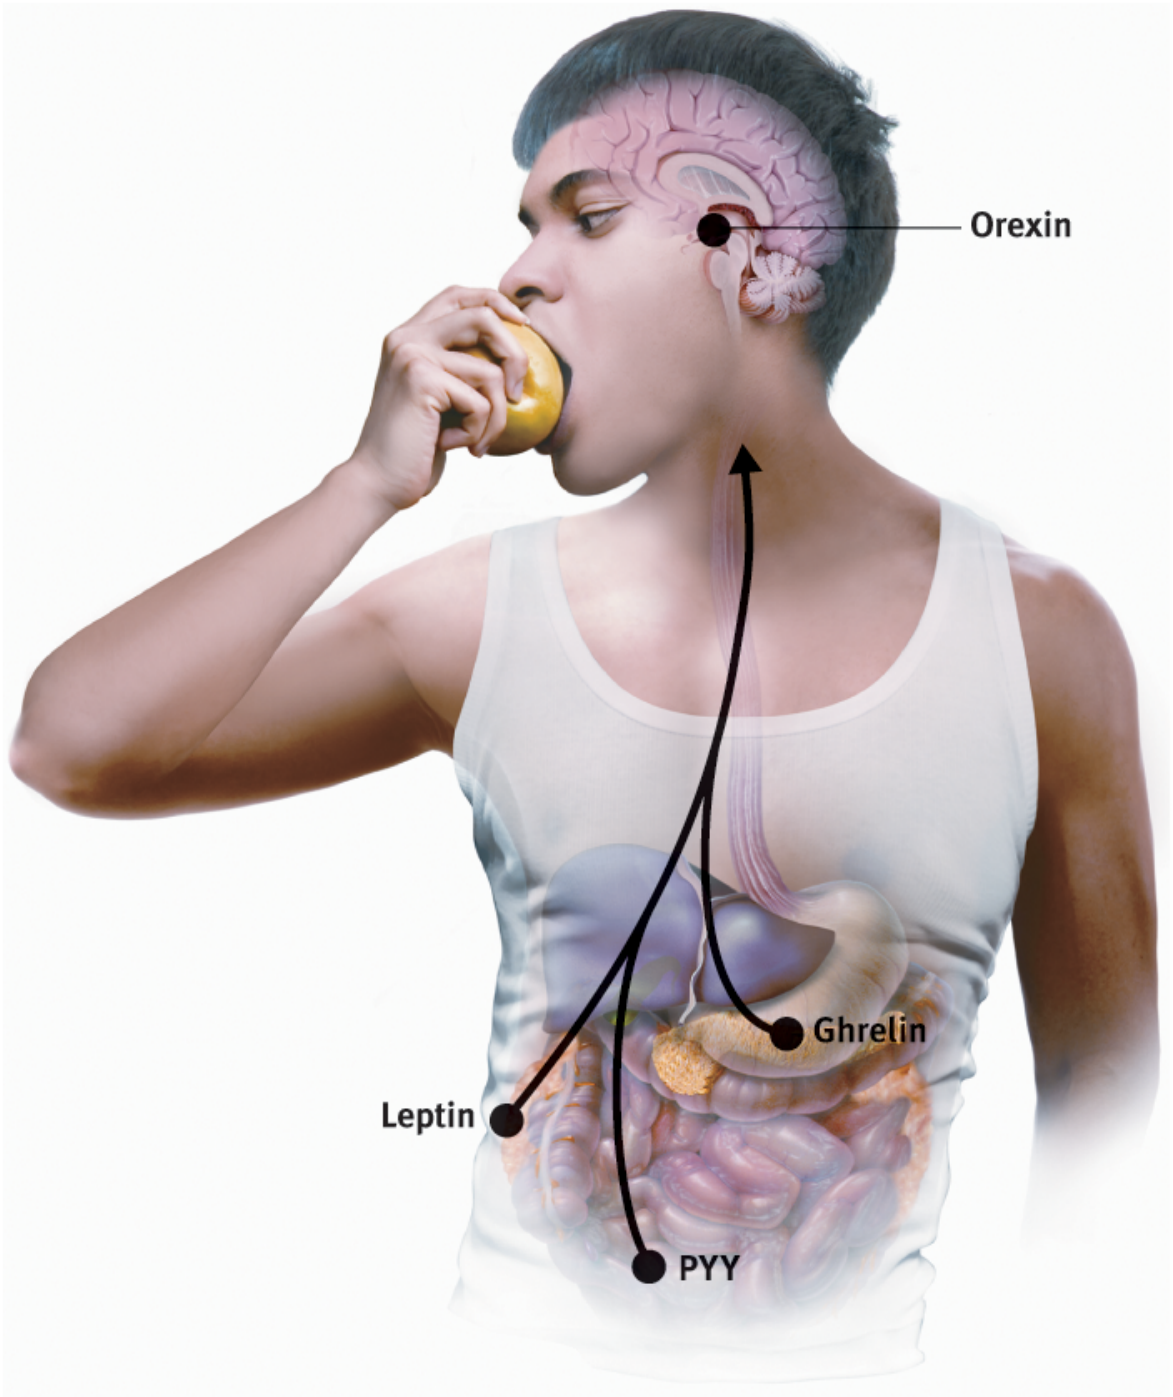
Extended description for FIGURE 33.1 Monitoring stomach contractions



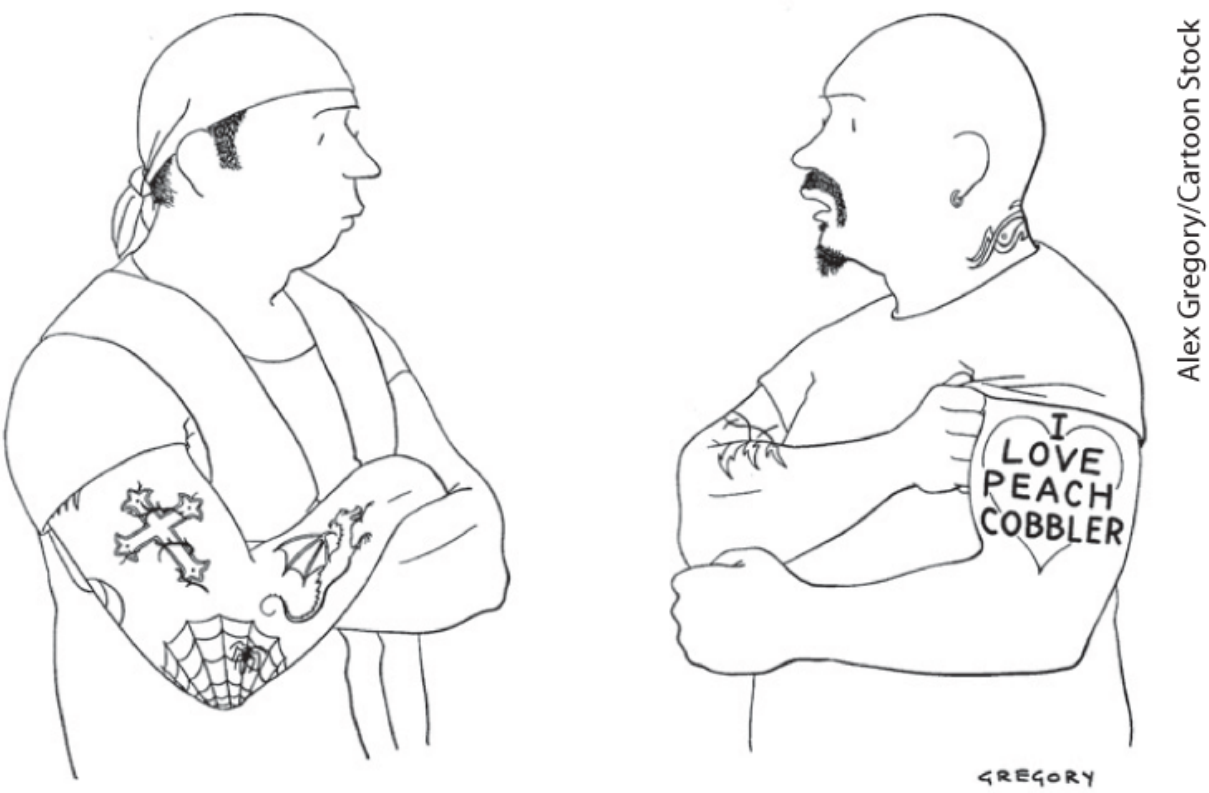
The illustration shows a man sitting at a table with a tube inserted in his mouth. He has a finger on a red button attached to an instrument on the table. A tube is depicted inside his throat, ending in a balloon in his stomach. A callout pointing toward the balloon reads, Washburn swallows balloon, which measures stomach contractions. A callout pointing toward the instrument with the red button on the table reads, Washburn presses key each time he feels hungry. A graph beside the image shows time in minutes ranging from 0 to 10 on the horizontal axis. Bars depicted along the horizontal axis indicate hunger pangs at different intervals. Pangs

are indicated between minutes 1 and 2, slightly after minute 3, most of the interval between minutes 4 and 5, just before and after minute 6, between minutes 7 and 8, and for most of the time between minutes 9 and 10. Waves depicted along the horizontal axis indicate stomach contractions as a pattern of sharp peaks and sudden downward slopes formed at different intervals.

Return to FIGURE 33.1 Monitoring stomach contractions

Extended description for FIGURE 33.3 The

appetite hormones



© Worth Publishers

The illustration shows a man eating a fruit. His brain and intestine are displayed. A callout pointing toward his brain just underneath the hypothalamus reads, Orexin. Different regions of his digestive system are labeled as follows, Ghrelin (in the stomach), P Y Y (in the intestines), and Leptin (fat cells in the abdomen). These three labels all point up toward the man's throat.

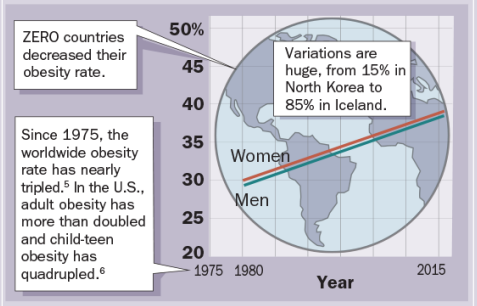
Extended description for Challenges of

obesity

© Worth Publishers

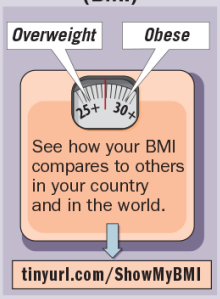
Thinking Critically About:

The Challenges of Obesity and Weight Control



Obesity and Its Health Effects

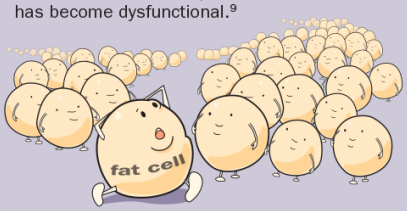
Obesity is associated with:



- **physical health risks**, including diabetes, high blood pressure, heart disease, gallstones, arthritis, and certain types of cancer.[1]
- **increased depression,** especially among women.[2]
- **bullying,** outranking race and sexual orientation as the biggest reason for youth bullying in Western cultures.[3]

Percentage Overweight in 195 Countries Studied[4]

Body Mass Index (BMI)



How Did We Get Here?

Does obesity reflect a simple lack of willpower, as some people presume?[7]
No. Many factors contribute to obesity.

PHYSIOLOGY FACTORS

Storing fat was adaptive.

- This ideal form of stored energy carried our ancestors through periods of famine. People in some impoverished places still find heavier bodies attractive, as plumpness signals affluence and status.[8]
- In food-rich countries, the drive for fat has become dysfunctional.[9]

Set point and metabolism matter.

- Fat (lower metabolic rate than muscle) requires less food intake to maintain than it did to gain.
- If weight drops below *set point/settling point*, the brain triggers more hunger and a slowed metabolism.
  - Body perceives STARVATION; adapts by burning fewer calories. Most dieters in the long run regain what they lose on weight-loss programs.[10]
  - After 30 weeks of competition on TV's *The Biggest Loser*, 6 years later only 1 of 14 contestants had kept the weight off. On average, they regained 70% of what they lost, and their metabolism remained slow.[11]

Genes influence us.

- Lean people seem naturally disposed to move about, burning more calories than energy-conserving overweight people, who tend to sit still longer.[12]
- Adoptive siblings' body weights are uncorrelated with one another or with their adoptive parents, instead resembling their biological parents' weight.[13]
- Identical twins have closely similar weights, even if raised apart.[14] Much lower *fraternal* twin weight correlation suggests genes explain 2/3 of our varying body mass.[15]
- More than 100 genes have been identified as each affecting weight in some small way.[16]

ENVIRONMENTAL FACTORS

- **Sleep loss** makes us more vulnerable to obesity.[17]

- **Social influences:** Our own odds of becoming obese triple if a close friend becomes obese.[18]
- **Food and activity levels:** Worldwide, we eat more energy-dense foods and we move less, with 31% of adults (including 43% of Americans and 25% of Europeans) now sedentary—averaging <20 minutes per day of moderate activity such as walking.[19]

NOTE: With weight, as with intelligence and other characteristics, there can be high levels of *heritability* (genetic influence on *individual* differences) without heredity explaining *group* differences. Genes mostly determine why one person is heavier than another. Environment mostly determines why people today are heavier than people were 50 years ago.

1. Kitahara et al., 2014. 2. Haynes et al., 2019; Jung et al., 2017; Rivera et al., 2017. 3. Puhl et al., 2015. 4. GBD, 2017. 5. NCD, 2016. 6. Flegal et al., 2010, 2012, 2016. 7. NORC, 2016. 8. Furnham & Baguma, 1994; Nettle et al., 2017; Swami, 2015. 9. Hall, 2016. 10. Mann et al., 2015. 11. Fothergill et al., 2016. 12. Levine et al., 2005. 13. Grilo & Pogue-Geile, 1991. 14. Hjelmborg et al., 2008; Plomin et al., 1997. 15. Maes et al., 1997. 16. Akiyama et al., 2017. 17. Keith et al., 2006; Nedeltcheva et al., 2010; Taheri, 2004; Taheri et al., 2004. 18. Christakis & Fowler, 2007. 19. Hallal et al., 2012.

The infographic is divided into the following two panels. The title in the first panel reads, **Obesity and Its Health Effects.** The text reads, Obesity is associated with: Bullet point 1, **Physical health risks,** including diabetes, high blood pressure, heart disease, gallstones, arthritis, and certain types of cancer (Kitahara et al., 2014). Bullet point 2, **Increased depression,** especially among women (Haynes, et al., 2019; Jung et al., 2017; Rivera et al., 2017). Bullet point 3, **Bullying,** outranking race and sexual orientation as the biggest reason for youth bullying in Western cultures (Puhl et al., 2015). An illustration shows a young woman eating a doughnut. A line graph titled, **Percentage Overweight in 195 Countries Studied** (G B D, 2017) is illustrated on a backdrop of the globe. The horizontal axis is labeled Year, starting at 19 75 and ending at 2015. The vertical axis represents percentage, starting at 20 percent and ending at 50 percent, in increments of 5. A line representing women starts at around 30 percent in 19 80 and rises linearly to 39 percent in 2015. A line representing men starts at around 29.5 percent in 19 80 and rises linearly to 38 percent in 2015. A text box in the graph reads, Variations are huge, from 15 percent in North Korea to 85 percent in Iceland. Outside the graph, a text box pointing toward the globe reads, ZERO countries decreased their obesity rate. Another text box pointing to the year 19 75 reads, since 19 75, the worldwide obesity rate has nearly tripled (N C D, 2016). In the U.S., adult obesity has more than doubled and child-teen obesity has quadrupled (Flegal et al., 2010, 2012, 2016). An illustration titled, **Body Mass Index (B M I)** shows a weighing scale. The weight window on the scale shows the B M I is 25 plus and 30 plus with a red line at the center between

both weights. A text box pointing toward 25 plus reads, overweight, and a text box pointing toward 30 plus reads, obese. Text on the scale reads, See how your B M I compares to others in your country and in the world. An arrow pointing downward reads, tinyurl dot com slash ShowMyBMI.

The title for the second panel reads, **How Did We Get Here?** Beside the title, the text reads, Does obesity reflect a simple lack of willpower, as some people presume? (N O R C, 2016 b). ***NO.*** Many factors contribute to obesity. Under this is the subtitle, **PHYSIOLOGY FACTORS.** Three sections with bullet points are under the subtitle. The first bulleted list heading reads, **Storing fat was adaptive.** Bullet point 1, This ideal form of stored energy carried our ancestors through periods of famine. People in some impoverished places still find heavier bodies attractive, as plumpness signals affluence and status (Furnham and Baguma, 19 94; Nettle et al, 2017; Swami, 2015). Bullet point 2, In food-rich countries, the drive for fat has become dysfunctional (Hall, 2016). The second bulleted list heading reads, **Set point and metabolism matter.** Bullet point 1, Fat (lower metabolic rate than muscle) requires less food intake to maintain than it did to gain. Bullet point 2, If weight drops below *set point slash settling point,* the brain triggers more hunger and a slowed metabolism. Bullet point 3, Body perceives STARVATION; adapts by burning fewer calories. Most dieters in the long run regain what they lose on weight-loss programs (Mann et al., 2015). Bullet point 4, After 30 weeks of competition on T V's *The Biggest Loser*, 6 years later,

Only 1 of 14 contestants had kept the weight off. On average, they regained 70 percent of what they lost, and their metabolism remained slow (Fothergill et al., 2016). The third bulleted list heading reads, **Genes influence us.** Bullet point 1, Lean people seem naturally disposed to move about, burning more calories than energy-conserving overweight people, who tend to sit still longer (Levine et al., 2005). Bullet point 2, Adoptive siblings' body weights are uncorrelated with one another or with their adoptive parents, instead resembling their biological parents' weight (Grilo and Pogue-Geile, 19 91). Bullet point 3, Identical twins have closely similar weights, even if raised apart (Hjelmborg et al., 2008; Plomin et al., 19 97). Much lower *fraternal* twin weight correlation suggests genes explain two-thirds of our varying body mass (Maes et al., 19 97). Bullet point 4, More than 100 genes have been identified as each affecting weight in some small way (Akiyama et al., 2017). The cartoon in this panel shows a large group of round, yellow fat cells all following their fat-cell leader.

Still in the **How Did We Get Here?** panel is another section, titled, **ENVIRONMENTAL FACTORS.** A bulleted list begins. Bullet point 1, **Sleep loss** makes us more vulnerable to obesity (Keith et al., 2006; Nedeltcheva et al., 2010; Taheri, 2004; Taheri et al., 2004). Below, three cartoonish oval shapes have eyes and mouths, all holding forks, with napkins tucked under their chins. Over these shapes is the word, ***Increasing***. Under these shapes is the caption, **Ghrelin** dash appetite-stimulating stomach hormone. Next, a left-facing

arrow points back to the ghrelin shapes from an illustration of a gray cloud with broken zees (representing broken sleep) around the words Sleep deprivation. After the sleep-deprivation cloud is a right-facing arrow pointing to three bespectacled oval shapes with closed eyes, wiping their mouths with handkerchiefs. These shapes decrease in size. Over these leptin shapes is the word, ***Decreasing***. Under the shapes is the caption, **Leptin** dash reports body fat to the brain. The illustrations show how sleep-deprivation causes ghrelin, the appetite-stimulating hormone, to increase, and leptin, which reports body fat to the brain, decreases, resulting in weight gain. Bullet point 2, **Social influences:** Our own odds of becoming obese triple if a close friend becomes obese (Christakis and Fowler, 2007). Bullet point 3, **Food and activity levels:** Worldwide, we eat more energy-dense foods and move less, with 31 percent of adults (including 43 percent of Americans and 25 percent of Europeans) now sedentary dash averaging less than 20 minutes per day of moderate activity such as walking (Hallal et al., 2012). Beside this bulleted list is a **Note** that reads: With weight, as with intelligence and other characteristics, there can be high levels of *heritability* (genetic influence on *individual* differences) without heredity explaining *group* differences. Genes mostly determine why one person today is heavier than another. Environment mostly determines why people today are heavier than people were 50 years ago.

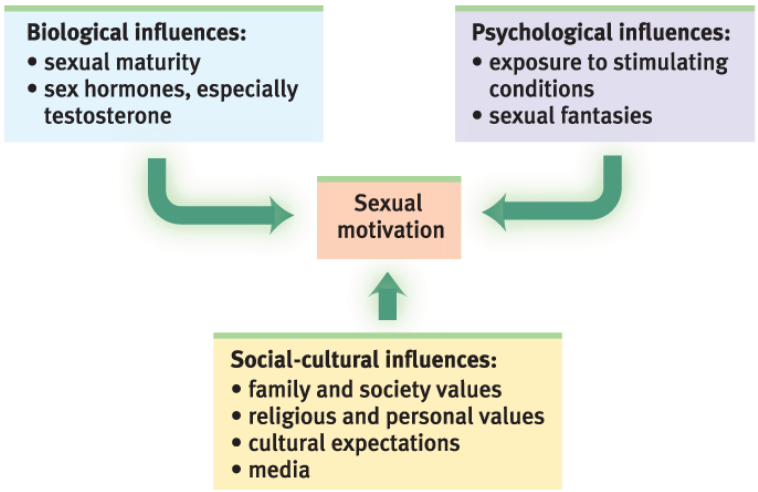
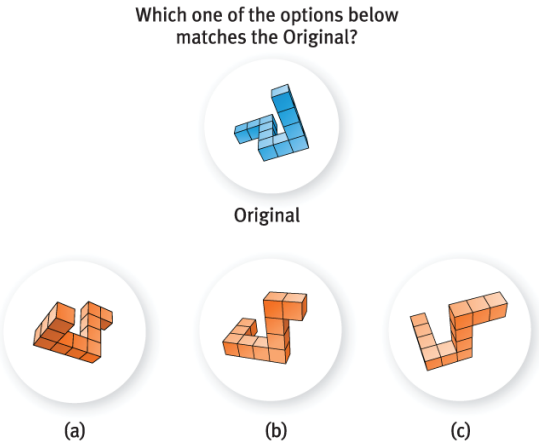
Extended description for FIGURE 34.1 Biopsychosocial influences on sexual motivation





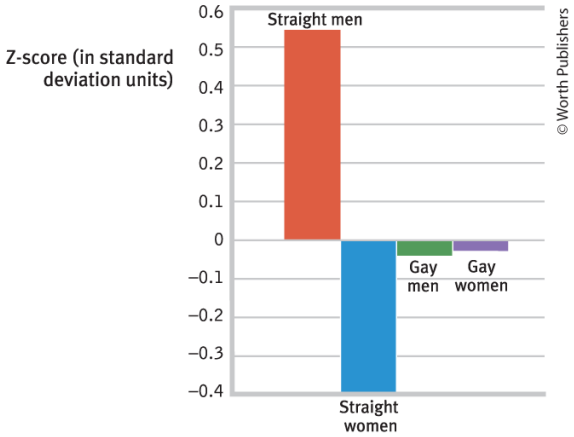


Photo: Digital Vision./Getty Images
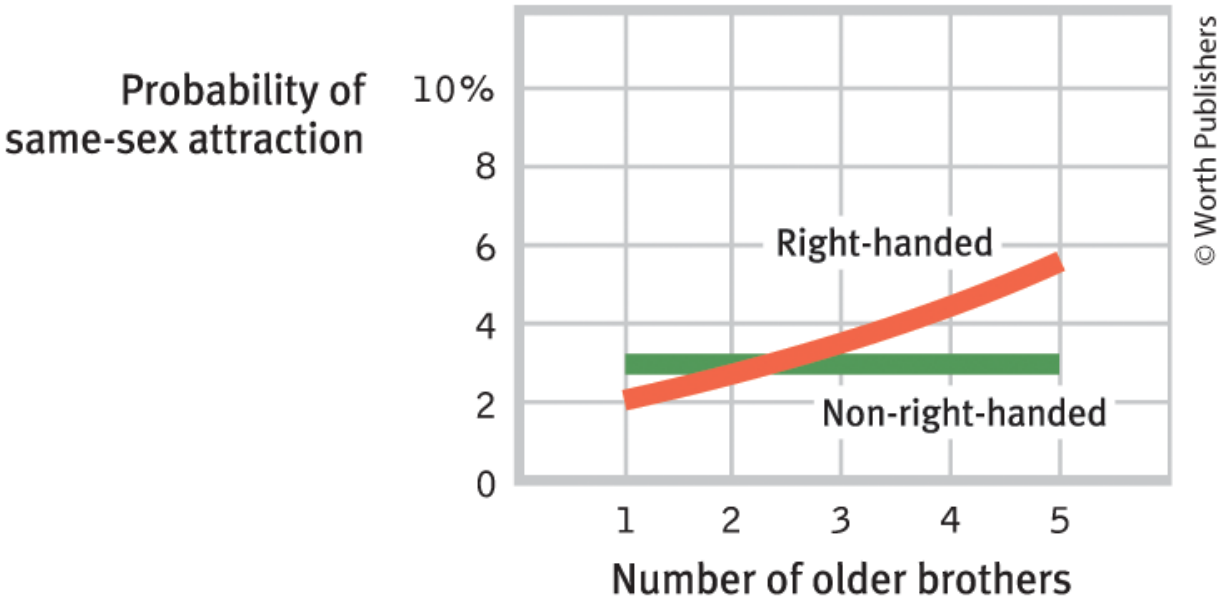
© Worth Publishers

A text box at the top left reads, **Biological influences:** sexual maturity, and sex hormones, especially testosterone. A text box at the top left reads, **Psychological influences:** exposure to stimulating conditions, and sexual fantasies. A text box at the bottom reads, **Socio-cultural influences:** family and society values, religious and personal values, cultural expectations, and media. All three text boxes point to a central text box reading, **Sexual motivation.**

Return to FIGURE 34.1 Biopsychosocial influences on sexual motivation

Extended description for FIGURE 34.2 Spatial abilities and sexual orientation

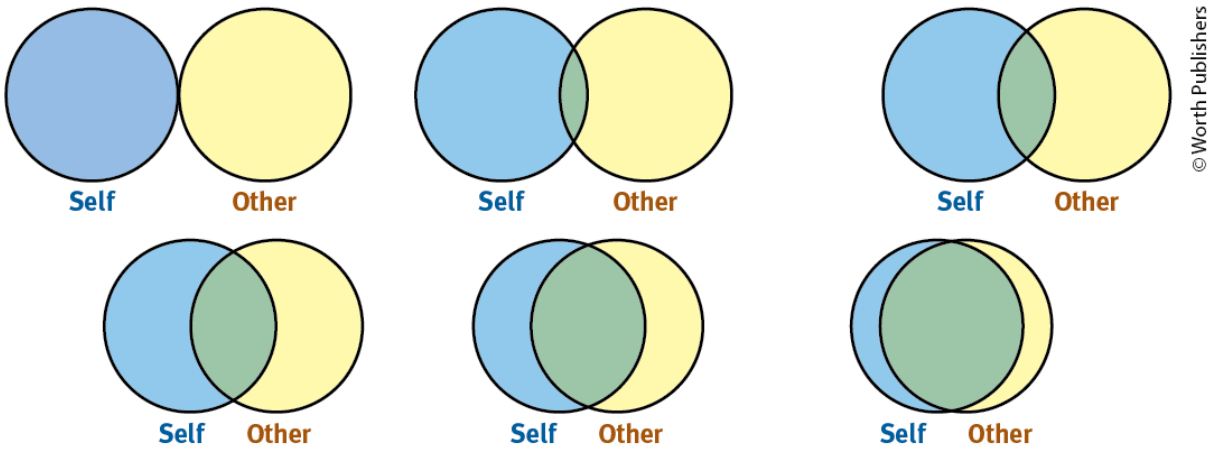


In the puzzle, a text above reads, Which one of the options below matches the Original? A 3-D shape labeled Original consists of cubes connected as follows: 3 cubes right, 4 cubes forward, 3 cubes right, and 4 cubes up. Below, three other shapes are as follows: (a) 3 cubes back, 4 cubes right, 4 cubes up, and 2 cubes right; (b) 3 cubes forward, 4 cubes right, 4 cubes high, and 2 cubes right; (c) 4 cubes forward, 3 cubes right, 4 cubes up, and 3 cubes right.

In the graph, the horizontal axis identifies sexual orientations as straight men, straight women, gay men, and gay women. The vertical axis identifies the Z-score (in standard deviation units) ranging from negative 0.4 to 0.6. Straight men have a Z-score between 0.5 and 0.6, whereas straight women have a Z-score of

negative 0.4. The Z-score of gay men is negative 0.04 and of gay women is negative 0.02. All data are approximate.

Return to FIGURE 34.2 Spatial abilities and sexual orientation

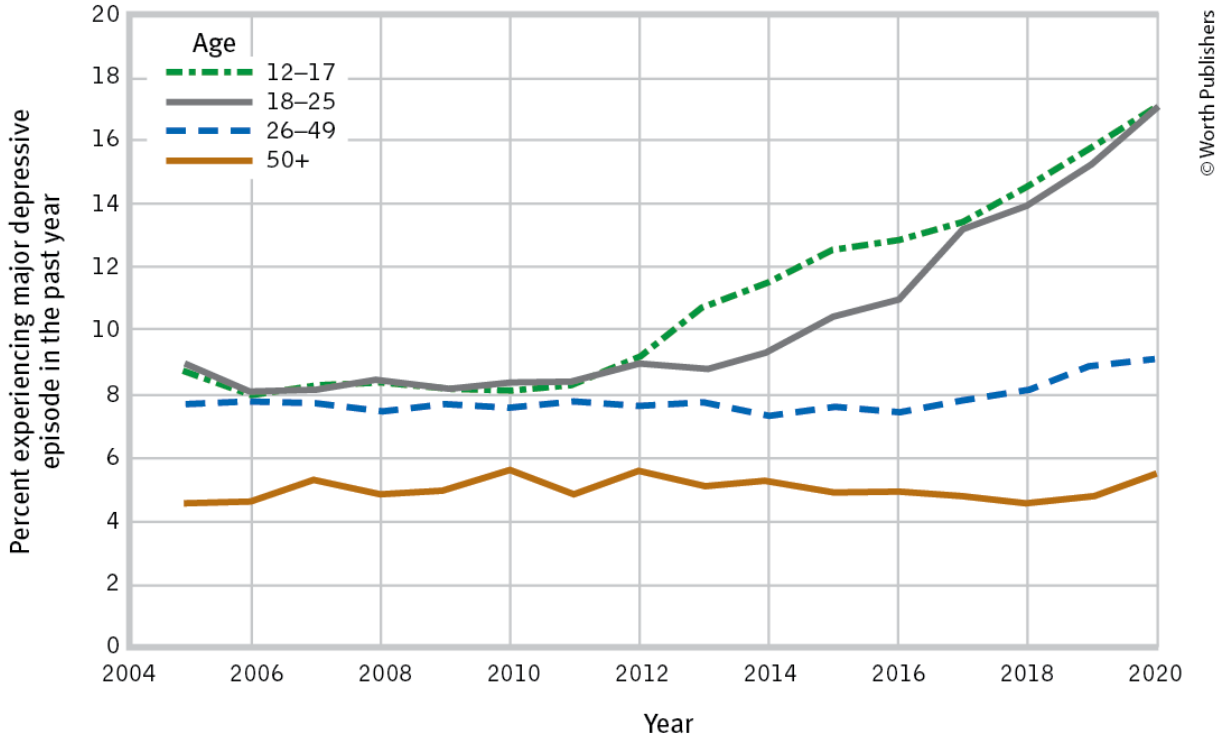


Extended description for FIGURE 34.3 The older-brother effect

The horizontal axis identifies the number of older brothers ranging from 0 to 5. The vertical axis identifies the probability of same-sex attraction ranging from 0 to 10 percent. The positive curve labeled right-handed starts from (1, 2); passes through (2, 3), (3, 3.5), (4, 4.5); and ends at (5, 5.5). The line labeled non-right-handed starts from (1, 3); passes through (2, 3), (3, 3), (4, 3); and ends at (5, 3). All data are approximate.

Return to FIGURE 34.3 The older-brother effect

Extended description for FIGURE 35.1 Inclusion of other in self (I O S) scale

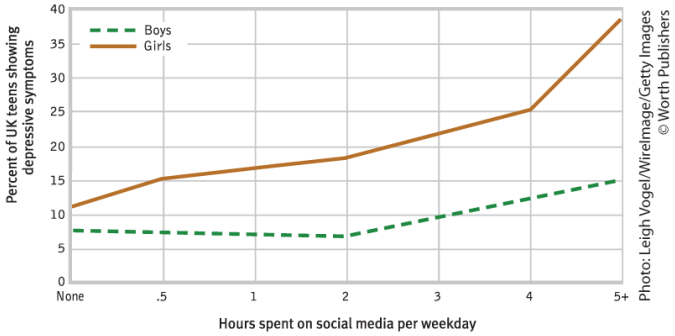


© Worth Publishers

The illustration shows six sets of two circles with the blue circle labeled self and the yellow circle labeled other. The first set shows them side by side, barely touching at the edges. From the second to the sixth set of circles, they start to overlap progressively more and more until self and other almost envelope each other. The overlapped region in each set is shaded in green.

Return to FIGURE 35.1 Inclusion of other in self (I O S) scale

Extended description for FIGURE 35.2 Rise in depression coincides with rise of smartphones

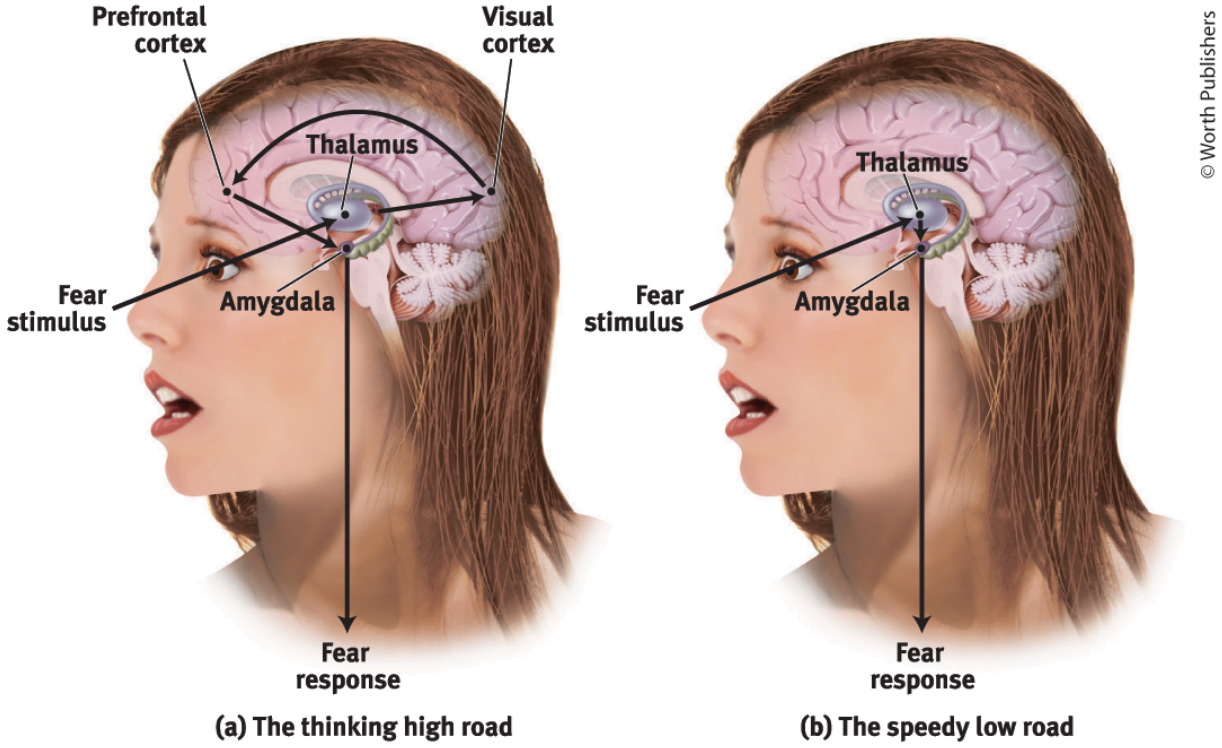


The horizontal axis represents year and ranges from 2004 to 20 20, in increments of 2. The vertical axis represents percent experiencing major depressive episode in the past year and ranges from 0 to 20, in increments of 2. A curve for age 12 to 17-year- olds starts at (2005, 9), drops to (2006, 8), remains steady until 2011 when it begins to rise sharply to (2013, 11) and steadily increases to end at (20 20, 17). A curve for age 18 to 25-year- olds begins at (2005, 9), drops to (2006, 8),

and follows the path of 12 to 17-year-olds until it slowly begins to increase at (2014, 9.5) to (2015, 11). The curve increases to (2017, 13) and ends at (20 20, 17). A curve for age 26 to 49-year- olds starts at (2005, 7.8), remains steady with a small drop in 2014 then increases slightly in 2019 to 9 percent ending at (20 20, 9.2). A curve for age 50 plus begins at (2005, 4.5), increases to its high peak at (2010, 5.8), drops slightly and increases again to (2012, 5.8), drops again, and remains steady until (20 20, 5.8). All data are approximate.

Return to FIGURE 35.2 Rise in depression coincides with rise of smartphones

Extended description for FIGURE 35.3 Depression and teen screens



The horizontal axis represents hours spent on social media per weekday and is labeled none, 0.5, 1, 2, 3, 4, 5 plus. The vertical axis represents percent of U K teens showing depressive symptoms and ranges from 0 to 40, in increments of 5. A curve for girls starts from (none, 11); passes through (.5, 15), (1, 17.5), (2, 19), (3, 22); (4, 25); and ends at (5 plus, 38). A curve for boys starts from (none, 7); drops to (2, 6); and increases steadily to end at (5 plus, 15). All data are approximate.

Return to FIGURE 35.3 Depression and teen screens

Extended description for FIGURE 36.1 The brain's pathways for emotions

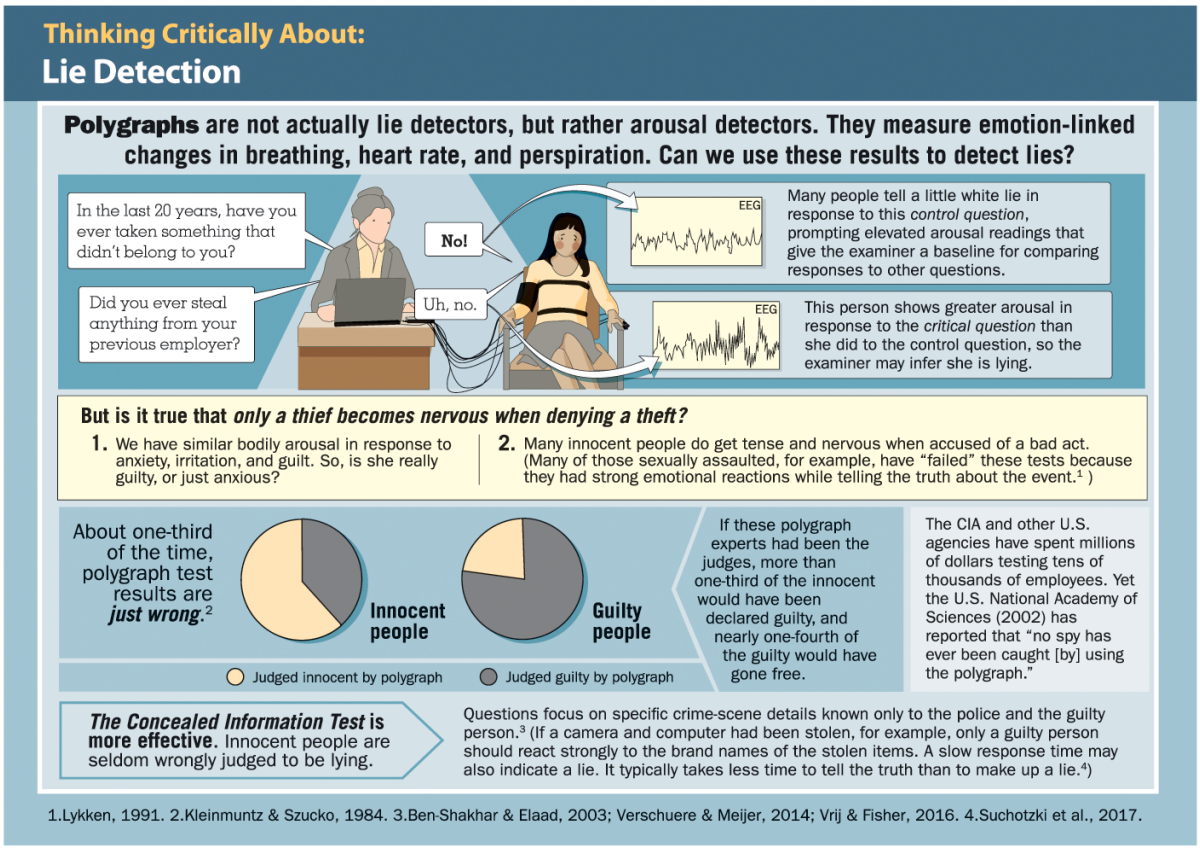
The left-hand profile is labeled (a) The thinking high road. A fear stimulus travels through the thalamus to the visual cortex, then to the prefrontal cortex, which leads to the amygdala, leading to a fear response. The right-hand profile is labeled, (b) The speedy low road. A fear stimulus travels through the thalamus to the amygdala, leading to a fear response.

Return to FIGURE 36.1 The brain's pathways for emotions

Extended description for FIGURE 36.2 Emotional arousal

Autonomic Nervous System Controls Physiological Arousal

Sympathetic division (arousing)		Parasympathetic division (calming)
Pupils dilate	EYES	Pupils contract
Decreases	SALIVATION	Increases
Perspires	SKIN	Dries
Increases	RESPIRATION	Decreases
Accelerates	HEART	Slows
Inhibits	DIGESTION	Activates
Secrete stress hormones	ADRENAL GLANDS	Decrease secretion of stress hormones
Reduced	IMMUNE SYSTEM FUNCTIONING	Enhanced



© Worth Publishers

The top of the table is entitled, **Autonomic Nervous System Controls Physiological Arousal.** Two illustrations are depicted. The illustration on the left shows the son almost tripping at the edge of a dock near a body of water, and the father reaching out to catch him. The Sympathetic division (arousing) is depicted as follows: EYES: Pupils dilate, SALIVATION: Decreases, SKIN: Perspires, RESPIRATION: Increases, HEART: Accelerates, DIGESTION: Inhibits, ADRENAL GLANDS: Secrete stress hormones, and IMMUNE SYSTEM FUNCTIONING: Reduced. The illustration on the right shows the father kneeling and holding his son close to him on the dock. The parasympathetic division (calming) is depicted as follows: EYES: Pupils contract, SALIVATION: Increases, SKIN: Dries,

RESPIRATION: Decreases, HEART: Slows, DIGESTION: Activates, ADRENAL GLANDS: Decrease secretion of stress hormones, and IMMUNE SYSTEM FUNCTIONING: Enhanced.

Return to FIGURE 36.2 Emotional arousal

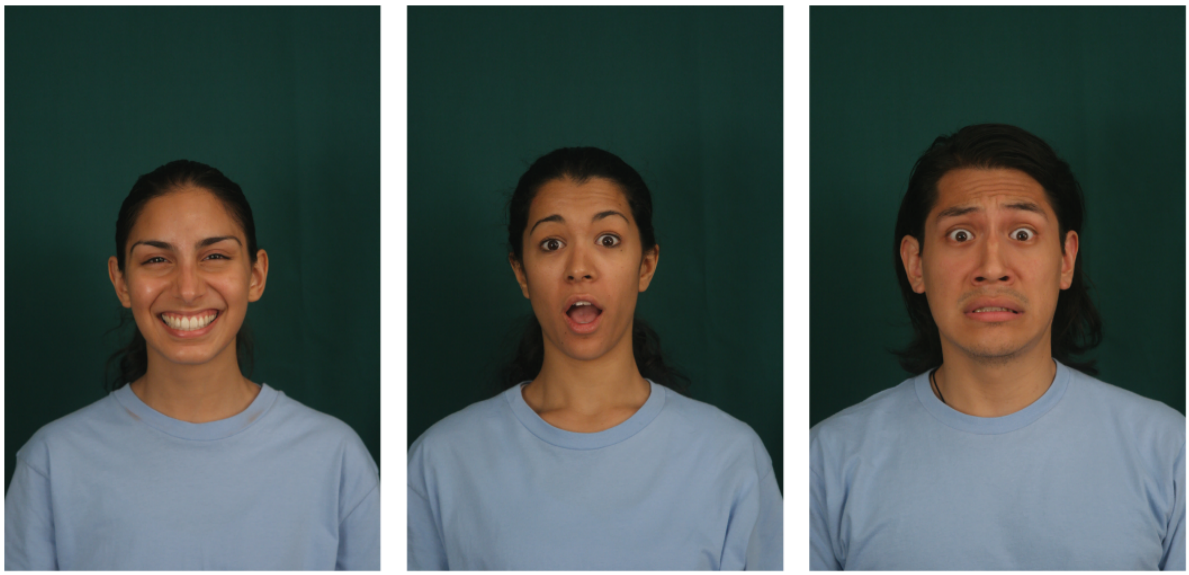
Extended description for Lie detection

© Worth Publishers

The infographic is divided into three panels. At the top of the first panel a text reads, **Polygraphs** are not actually lie detectors, but rather arousal detectors. They measure emotion-linked changes in breathing, heart rate, and perspiration. Can we use these results to detect lies? Below, an illustration shows a worried-looking woman sitting in a chair with polygraph test wires attached to her. The wires lead to a polygraph machine on a table where another woman sits, administering the polygraph test. In a text box pointing to the test

examiner, the examiner asks the woman taking the test, In the last 20 years, have you ever taken something that didn't belong to you? In another text box pointing to the test taker, is the word, No! From there, an arrow points to a box with an illustration of an E E G scan showing the waves of the test taker's brain activity. Text reads, Many people tell a little white lie in response to this *control question*, prompting elevated arousal readings that give the examiner a baseline for comparing responses to other questions. In another text box pointing at the examiner, the question reads, Did you ever steal anything from your previous employer? In a text box pointing to the test taker, the answer reads, Uh, no. From there, an arrow points to a box with an illustration of the higher waves of elevated brain activity. Text reads, This person shows greater arousal in response to the critical question than she did to the control question, so the examiner may infer she is lying.

In the second panel, text reads, **But is it true that *only a thief becomes nervous when denying a theft?*** Under this is a numbered list. 1. We have similar bodily arousal in response to anxiety, irritation, and guilt. So, is she really guilty, or just anxious? 2. Many innocent people do get tense and nervous when accused of a bad act. (Many of those sexually assaulted, for example, have "failed" these tests because they had strong emotional reactions while telling the truth about the event) (Lykken, 19 91).



In the third panel, a text reads, About one-third of the time, polygraph test results are **just wrong** (Kleinmuntz and Szucko, 19 84). Beside this text are two pie charts with yellow and gray sections. The yellow represents Judged innocent by polygraph. The gray represents Judged guilty by polygraph. The first pie chart is labeled **Innocent People**. More than two-thirds of the pie chart is yellow (indicating innocence). But almost one-third of the pie chart is gray (indicating guilt). The second pie chart is labeled **Guilty People**. A little more than three-quarters of the chart is gray (indicating guilt). And a little less than a quarter of the chart is yellow (indicating innocence). The text beside these pie charts reads, If these polygraph experts had been the judges, more than one-third of the innocent would have been declared guilty, and nearly one-fourth of the guilty would have gone free. To the right, another area of text says, The C I A and other U.S. agencies have spent millions of dollars testing tens of thousands of employees. Yet the U.S. National Academy of Sciences (2002) has reported that "no spy has ever been caught [by] using the polygraph."

At the bottom of the infographic is a large right-facing arrow with the text inside it, ***The Concealed Information Test* is more effective**. Innocent people are seldom wrongly judged to be lying. The arrow points to text, Questions focus on specific crime-scene details known only to the police and the guilty person (Ben-Shakhar and Elaad, 2003; Verschuere and Meijer, 2014; Vrij and Fisher, 2016). (If a camera and computer had been stolen, for example, only a guilty person should react strongly to the brand names of the stolen items.

A slow response time may also indicate a lie. It typically takes less time to tell the truth than to make up a lie) (Suchotzki et al., 2017).

Extended description for FIGURE 37.4 Cultural consensus in question

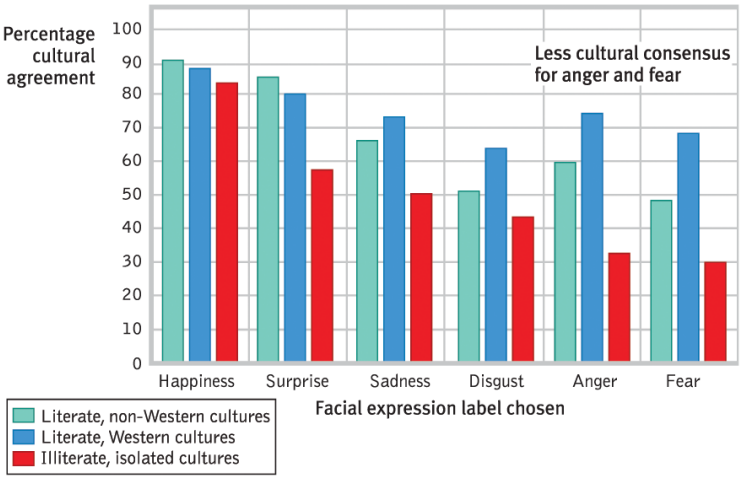

Photo: Roman Samborskyi/Alamy Stock Photo
© Worth Publishers

The horizontal axis is labeled facial expression label chosen and has areas for six emotions. They include happiness, surprise, sadness, disgust, anger, and fear. The vertical axis is labeled percentage cultural agreement and has values from 0 to 100, in increments of 10. Each emotion has three bars, representing the following: literate, non-Western cultures; literate, Western cultures; and illiterate, isolated cultures. The data are as follows:

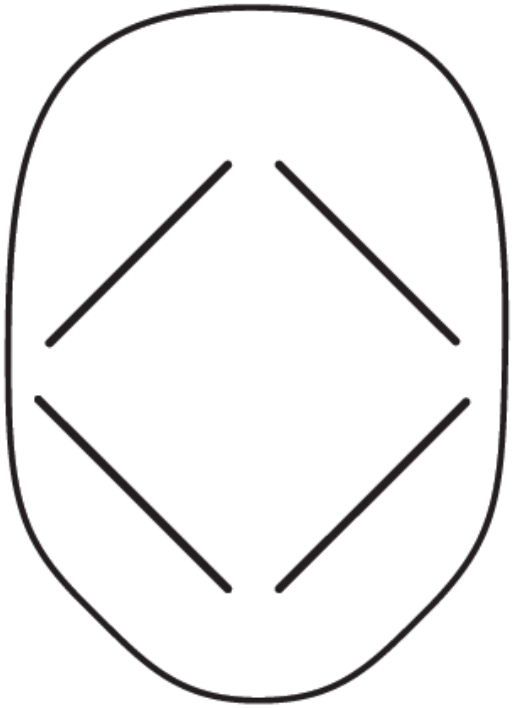
Happiness: Literate, Non-Western cultures, 90.5 percent; Literate, Western cultures, 89.5 percent; and Illiterate, Isolate cultures, 84 percent.

Surprise: Literate, Non-Western cultures, 87.5 percent; Literate, Western cultures, 80 percent; and Illiterate, Isolate cultures, 58 percent.

Sadness: Literate, Non-Western cultures, 67.5 percent; Literate, Western cultures, 72 percent; and Illiterate, Isolate cultures, 50.1 percent.

Disgust: Literate, Non-Western cultures, 50.2 percent; Literate, Western cultures, 64.5 percent; and Illiterate, Isolate cultures, 42.5 percent.

Anger: Literate, Non-Western cultures, 60 percent; Literate, Western cultures, 74 percent; and Illiterate, Isolate cultures, 32 percent.



Fear: Literate, Non-Western cultures, 49 percent; Literate, Western cultures, 69 percent; and Illiterate, Isolate cultures, 30 percent.

All data are approximate.

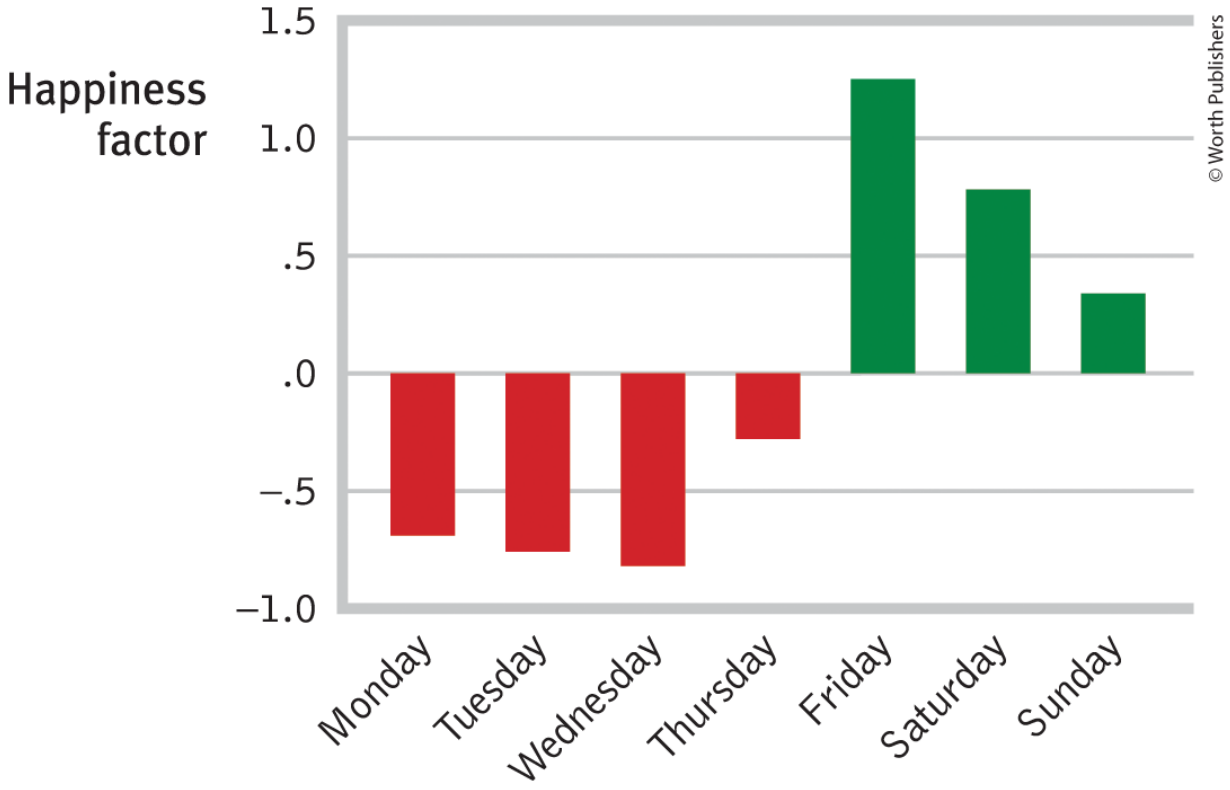
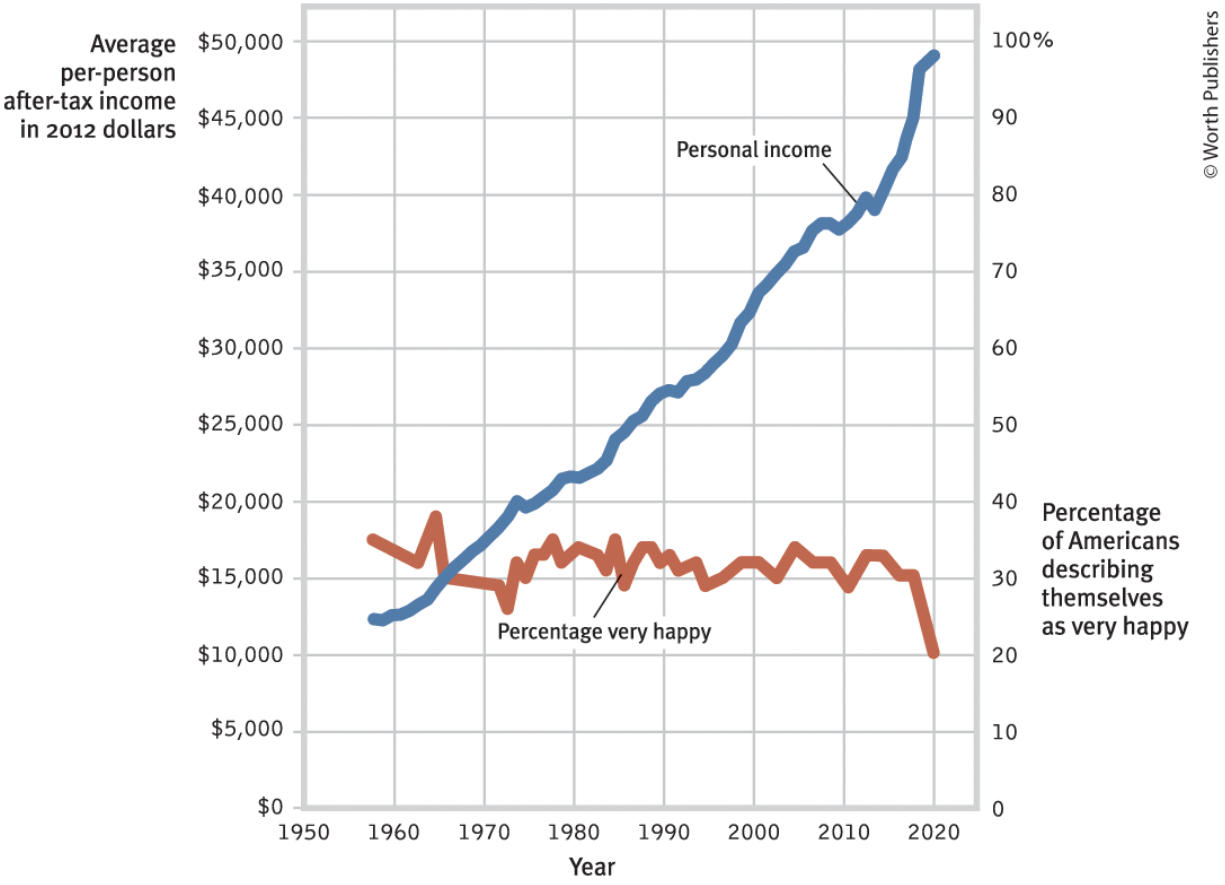
Extended description for FIGURE 38.2 A tale of two emotional dimensions



There are two dimensions represented by a vertical line and a horizontal line, crossed at 90-degree angles in the middle. At the top, a text box reads, **High arousal**; to the right, a text box reads, **Positive valence (pleasant)**; at the bottom, a text box reads, **Low arousal**; and to the left, a text box reads, **Negative valence (unpleasant)**.

There are four emotions in each of the four quadrants of this figure. The top right quadrant has the following, starting at the top and moving clockwise to the right: alert, excited, elated, and happy. The bottom right quadrant has the following, starting at the right and moving clockwise to the bottom: contented, serene, relaxed, and calm. The lower left quadrant has the following, starting at the bottom and moving clockwise to the left: fatigued, bored, depressed, and sad. The upper left quadrant has the following, starting at the left and moving clockwise to the top: upset, stressed, nervous, and tense.

Return to FIGURE 38.2 A tale of two emotional dimensions



Extended description for FIGURE 38.3 Emotion notification

The horizontal axis is labeled from Monday to Sunday. The vertical axis represents Happiness factor and ranges from negative 1.0 to positive 1.5, in increments of 0.5. The data are as follows: (Monday, negative 0.7); (Tuesday, negative 0.75); (Wednesday, negative 0.80); (Thursday, negative 0.25); (Friday, positive 1.25); (Saturday, positive 0.75); and (Sunday, positive 0.35). All data are approximate

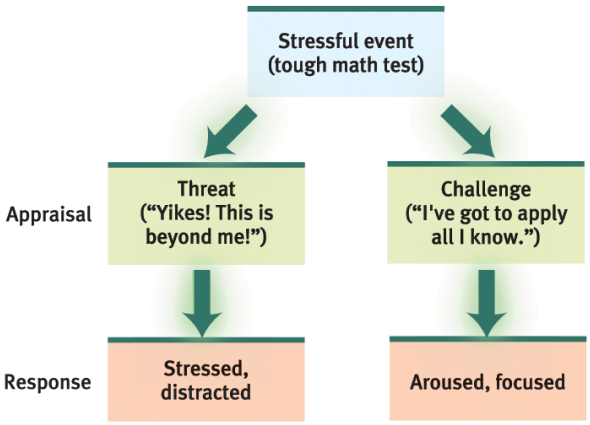
Extended description for FIGURE 39.1 Stress appraisal



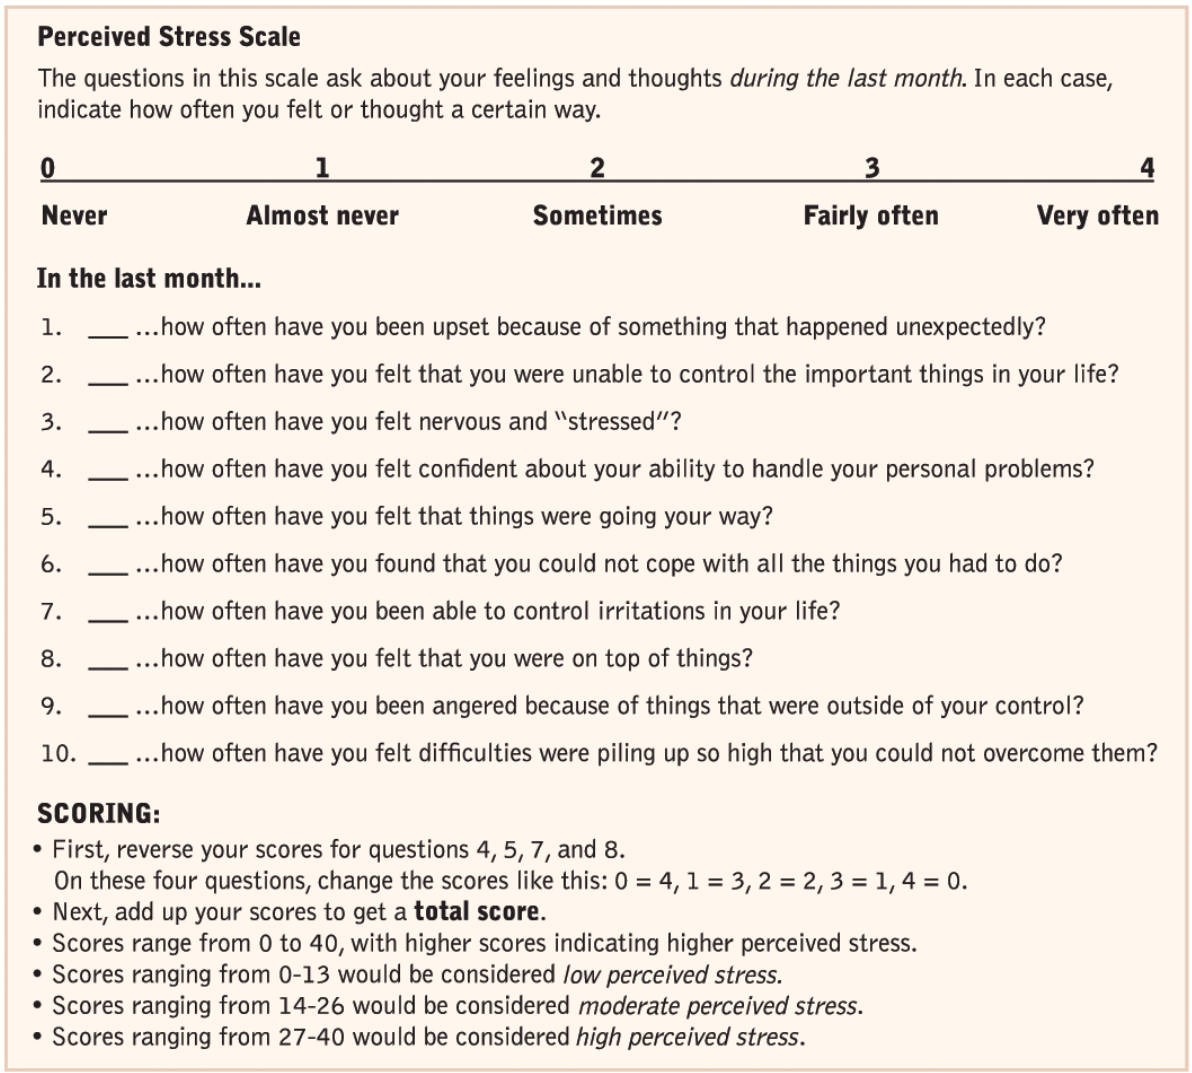


Photo: Fuse/Getty Images
© Worth Publishers

The flowchart shows Stressful event (tough math test), Appraisal, and Response. In the first path, the stressful event of a tough math test leads to an appraisal of threat (Yikes! This is beyond me!) that leads to a response of stressed and distracted. In the second path, the stressful event of a math test leads to the appraisal of challenge (I've got to apply all I know.) that leads to a response of aroused and focused.

Return to FIGURE 39.1 Stress appraisal

Extended description for FIGURE 39.2 Perceived Stress Scale

Perceived Stress Scale

The questions in this scale ask about your feelings and thoughts *during the last month*. In each case, indicate how often you felt or thought a certain way.

0	1	2	3	4
Never	Almost never	Sometimes	Fairly often	Very often

In the last month...

1. ___ ...how often have you been upset because of something that happened unexpectedly?
2. ___ ...how often have you felt that you were unable to control the important things in your life?
3. ___ ...how often have you felt nervous and "stressed"?
4. ___ ...how often have you felt confident about your ability to handle your personal problems?
5. ___ ...how often have you felt that things were going your way?
6. ___ ...how often have you found that you could not cope with all the things you had to do?
7. ___ ...how often have you been able to control irritations in your life?
8. ___ ...how often have you felt that you were on top of things?
9. ___ ...how often have you been angered because of things that were outside of your control?
10. ___ ...how often have you felt difficulties were piling up so high that you could not overcome them?

SCORING:

- First, reverse your scores for questions 4, 5, 7, and 8.
  On these four questions, change the scores like this: 0 = 4, 1 = 3, 2 = 2, 3 = 1, 4 = 0.
- Next, add up your scores to get a **total score**.
- Scores range from 0 to 40, with higher scores indicating higher perceived stress.
- Scores ranging from 0-13 would be considered *low perceived stress.*
- Scores ranging from 14-26 would be considered *moderate perceived stress*.
- Scores ranging from 27-40 would be considered *high perceived stress*.

© Worth Publishers

The survey is titled, **Perceived Stress Scale**. Text reads as follows: The questions in this scale ask about your feelings and thoughts

during the last month. In each case, indicate how often you felt or thought a certain way.

Under this text is a scale reading: **0, Never; 1, Almost never; 2, Sometimes; 3, Fairly often; 4, Very often.**

Under the scale the questions to be rated are as follows:

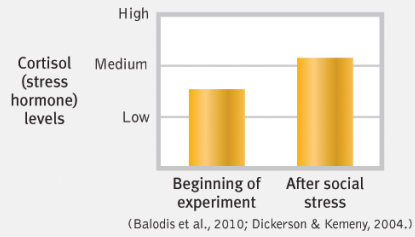
In the last month… 1. How often have you been upset because of something that happened unexpectedly? 2. How often have you felt that you were unable to control the important things in your life? 3. How often have you felt nervous and stressed? 4. How often have you felt confident about your ability to handle your personal problems? 5. How often have you felt that things were going your way? 6. How often have you found that you could not cope with all the things you had to do? 7. How often have you been able to control irritations in your life? 8. How often have you felt that you were on top of things? 9. How often have you been angered because of things that were outside of your control? 10. How often have you felt difficulties were piling up so high that you could not overcome them?

Scoring: First, reverse your scores for questions 4, 5, 7, and 8. On these four questions, change the scores like this: 0 equals 4, 1 equals 3, 2 equals 2, 3 equals 1, and 4 equals 0. Next, add up your scores to get a **total score**. Scores range from 0 to 40, with higher scores indicating higher perceived stress. Scores ranging from 0 to 13

would be considered *low perceived stress*. Scores ranging from 14 to 26 would be considered *moderate perceived stress*. Scores ranging from 27 to 40 would be considered *high perceived stress*.

Return to FIGURE 39.2 Perceived Stress Scale

Extended description for FIGURE 39.3 Studying stress



1. Participants chew gum so that collecting saliva is easy. The researcher takes a saliva sample from each participant at the beginning of the experiment to measure levels of the stress hormone *cortisol*.

2. Participant gives simulated job interview speech to a critical panel. Next, the participant is asked to complete difficult math problems out loud.

© Worth Publishers

3. Measuring cortisol in participants' saliva before and after tells us that although they enter the lab experiencing some stress, that level goes up 40 percent after they experience social stress.

4. Research team thanks and *debriefs* the participant—explaining the purpose of the experiment and the role she played.

The four-step model is as follows:

1. An illustration shows a researcher holding a clipboard as the participant spits into a test tube and returns it to the researcher. Accompanying text reads, Participants chew gum so that collecting saliva is easy. The researcher takes a saliva sample from each participant at the beginning of the experiment to measure levels of the stress hormone *cortisol*.

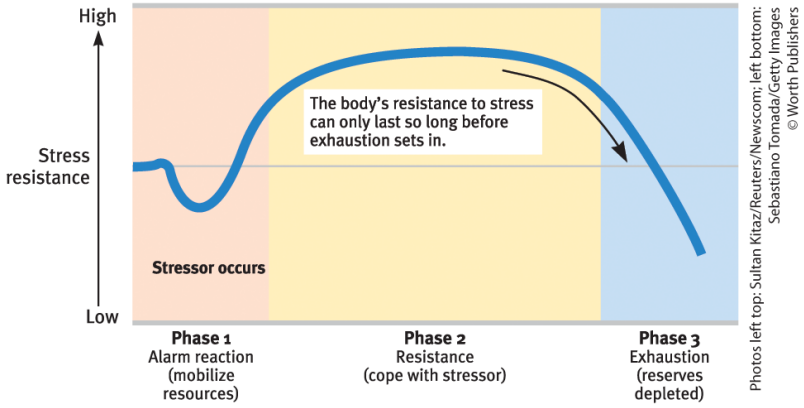
2. An illustration shows the participant giving a speech into a microphone at a podium in front of three people seated at a table. One of the observers asks the participant, What is 1223 minus 37? Accompanying text reads, Participant gives simulated job interview speech to a critical panel. Next, the participant is asked to compute difficult math problems out loud.

3. A bar graph is labeled Beginning of experiment and After social stress on the horizontal axis. The vertical axis represents Cortisol (stress hormone) levels and is labeled low, medium, and high from bottom to top. The bar for the beginning of the experiment goes to halfway between low and medium cortisol levels, and the bar for after social stress rises to just above the medium cortisol level. Accompanying text reads, Measuring cortisol in participants' saliva before and after tells us that although they enter the lab experiencing some stress, that level goes up 40 percent after they experience social stress.

4. An illustration shows the participant smiling and shaking hands with the panel while receiving a thank you written note. Accompanying text reads, Research team thanks and *debriefs* the participant - explaining the purpose of the experiment and the role she played.

Return to FIGURE 39.3 Studying stress

Extended description for Stress response system



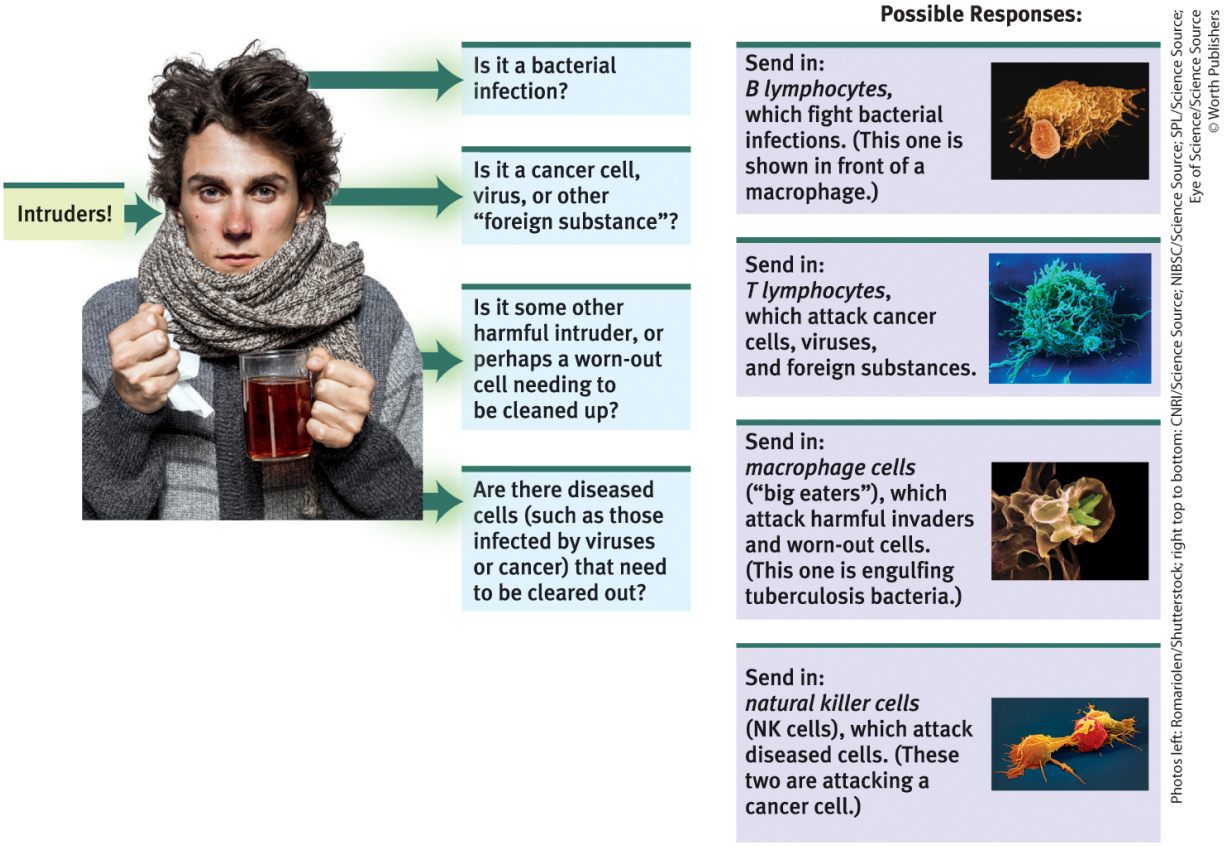
Roz Chast/Cartoon Stock

Above the five faces, a question reads, How is your terror today? The first face shows a wide smile; the text reads, Shhh. I am sleeping. The second face shows a moderate smile; the text reads, I am awake. The third face shows a slightly worried expression; the text reads, What? The fourth face shows a deeply worried face with wide eyes and a frightened frown; the text reads, WHAT? in all capital letters. The fifth face shows a highly terrified face with large, wide eyes that are trembling and a wide open mouth with teeth showing in a deep frown. Text reads, WHAT?!?! in all capital bold letters.

Return to Stress response system

Extended description for FIGURE 39.4 Selye's general adaptation syndrome

Photos left top: Sultan Kitaz/Reuters/Newscom; left bottom: Sebastiano Tomada/Getty Images
© Worth Publishers



In the graph, the horizontal axis is labeled **Phase 1**, Alarm reaction (mobilize resources); **Phase 2**, Resistance (cope with stressor); **Phase 3**, Exhaustion (reserves depleted). The vertical axis represents Stress resistance and ranges from low at the bottom to high at the top. The curve ranges from medium to high-stress resistance at phase 1. The phase one curve range is labeled, Stressor occurs. The curve rises to its highest level and then stays at a constant high level at phase 2. Right at the end of phase 2, the curve begins to drop. Accompanying text reads, The body's resistance to stress can only last so long before exhaustion sets in. The curve drops down to the lowest stress resistance at phase 3.

The top photo shows two men wearing helmets rescuing children and carrying them in their arms amid the rubble of a damaged building.

The bottom photo shows two of those rescuers looking depressed and anxious while seated in a building.

Return to FIGURE 39.4 Selye's general adaptation syndrome

Extended description for FIGURE 39.5 A simplified view of immune responses

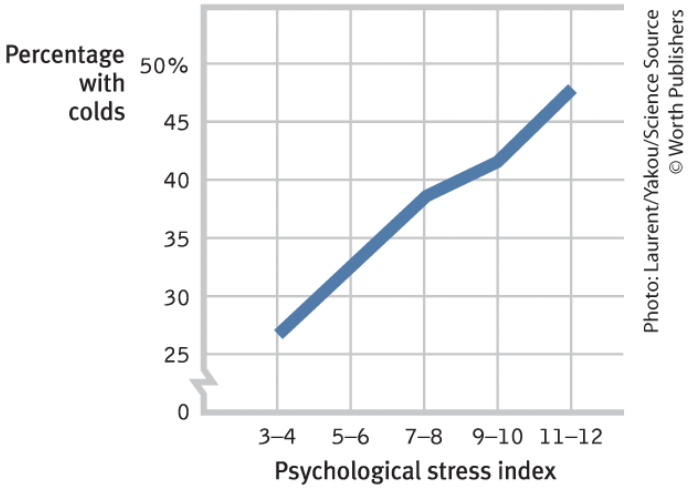
A photo on the left shows a man in a sweater and a scarf with a hot drink in one hand and a handkerchief in the other hand. To the left of the man, the word Intruders! is written with an arrow that points to him. Arrows from the man point right toward text boxes representing possibilities.

The text boxes read as follows from top to bottom: Is it a bacterial infection? Is it a cancer cell, virus, or other foreign substance? Is it some other harmful intruder, or perhaps a worn-out cell needing to be cleaned up? Are there diseased cells (such as those infected by viruses or cancer) that need to be cleared out?

The final column shows Possible Responses in boxes as follows from top to bottom. The first response reads, Send in: *B lymphocytes*, which fight bacterial infections. (This one is shown in front of a macrophage.) An electron micrograph shows B lymphocytes. The second response reads, Send in: *T lymphocytes*, which attack cancer cells, viruses, and foreign substances. An electron micrograph shows T lymphocytes. The third response reads, Send in: *macrophage cells* (big eaters), which attack harmful invaders and worn-out cells. (This one is engulfing tuberculosis bacteria.) An electron micrograph shows macrophage cells. The fourth response reads, Send in: *natural killer cells* (N K cells), which attack diseased cells. (These two are attacking a cancer cell.) An electron micrograph shows N K cells. Each response lines up approximately in order with the possible intruder.

Return to FIGURE 39.5 A simplified view of immune responses

Extended description for FIGURE 39.6 Stress and colds



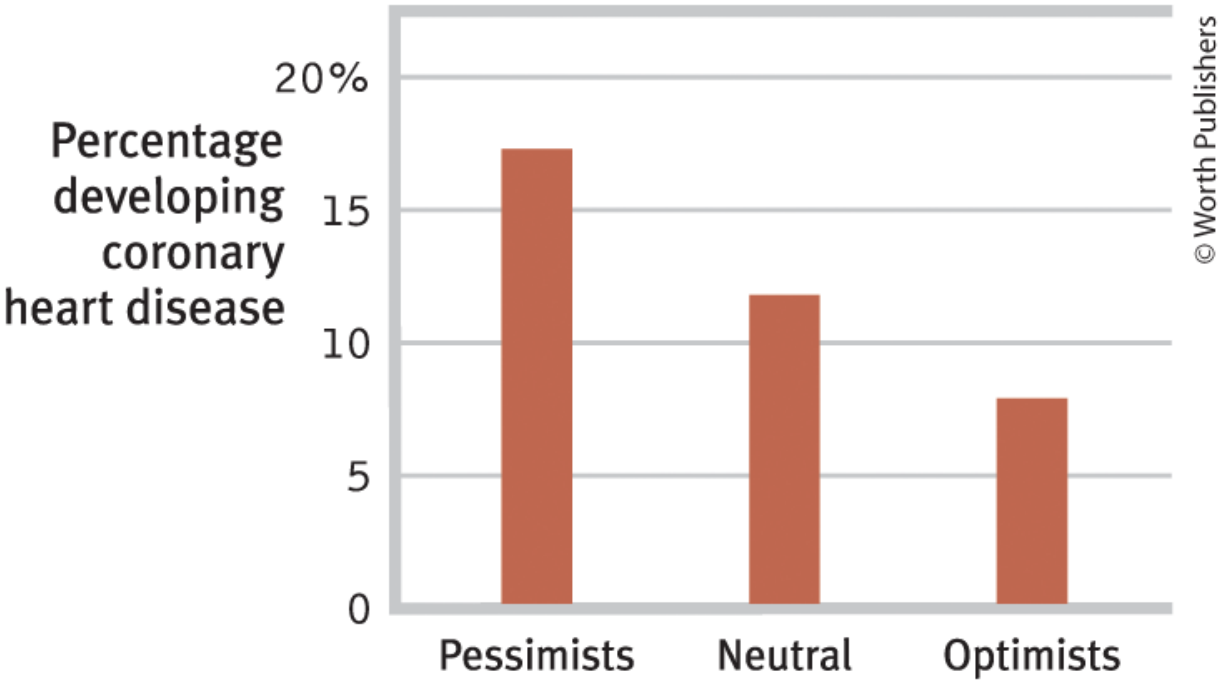


Photo: Laurent/Yakou/Science Source
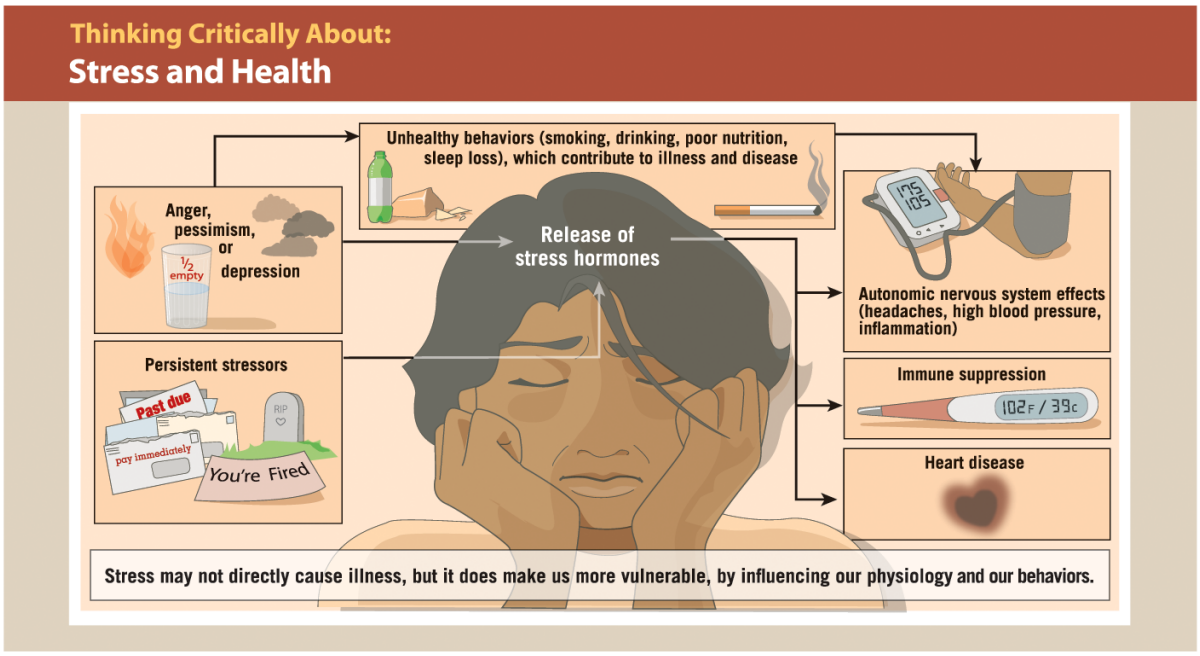
© Worth Publishers

The horizontal axis represents psychological stress index and is labeled 3 to 4, 5 to 6, 7 to 8, 9 to 10, and 11 to 12. The vertical axis represents percentage with colds and ranges from 0 to 50 percent, in increments of 5. Between 0 and 25 percent, there are no values. A line begins at 3 to 4 and is about 27 percent. It increases in a linear fashion to 7 to 8 where it is at 39 percent. The line then flattens slightly, and at 9 to 10 the value is 42 percent. It then increases again to 11 to 12 and 47.5 percent. All data are approximate.

Return to FIGURE 39.6 Stress and colds

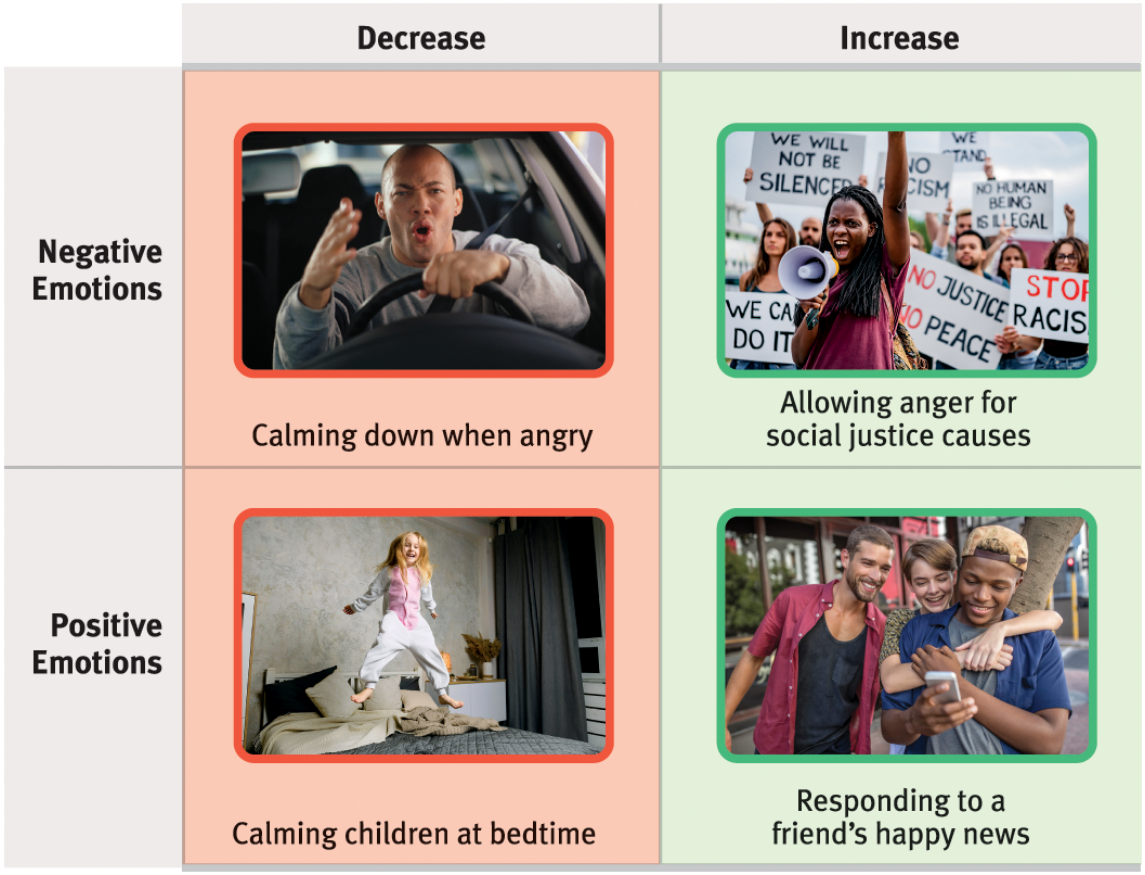


Extended description for FIGURE 39.7 Pessimism and heart disease

The horizontal axis is labeled Pessimists, Neutral, and Optimists. The vertical axis represents percentage developing coronary heart disease and ranges from 0 to 20 percent, in increments of 5. The data are as follows: Pessimists, 17 percent; Neutral, 12 percent; and Optimists, 8 percent. All data are approximate.

Return to FIGURE 39.7 Pessimism and heart disease

Extended description for Stress and health



© Worth Publishers

In the center of the infographic is an illustration showing a sad woman with clenched hands against both cheeks and eyes closed. A text overlaid on the head reads, Release of stress hormones. A box on the bottom left titled, Persistent stressors, shows overdue bills, a gravestone, and a pink slip with the words, you're fired. A box on the top left shows flames, dark clouds, and a half empty cup. Text reads: Anger, pessimism, or depression. Arrows point from the boxes to the text on the woman's head, Release of stress hormones. An arrow points from the top left box to a box on the top showing an open soft-drink bottle, an open bag of chips, and a lit cigarette. Text reads: Unhealthy behaviors (smoking, drinking, poor nutrition, sleep loss),

which contribute to illness and disease. An arrow from the text on the woman's head, Release of stress hormones, points to three boxes on the right. The box on the top right shows a sphygmomanometer with the cuff around an arm and the display reading 175 over 105. Text reads: Autonomic nervous system effects (headaches, high blood pressure, inflammation). The box on the middle right titled, Immune suppression, shows a thermometer with a reading of 102 degrees Fahrenheit or 39 degrees Celsius. The box on the middle right titled, Heart disease, shows a heart surrounded by blurry gray. An arrow also points from the box on the top to the box on the top right. A text box at the bottom of the infographic reads: Stress may not directly cause illness, but it does make us more vulnerable, by influencing our physiology and our behaviors.

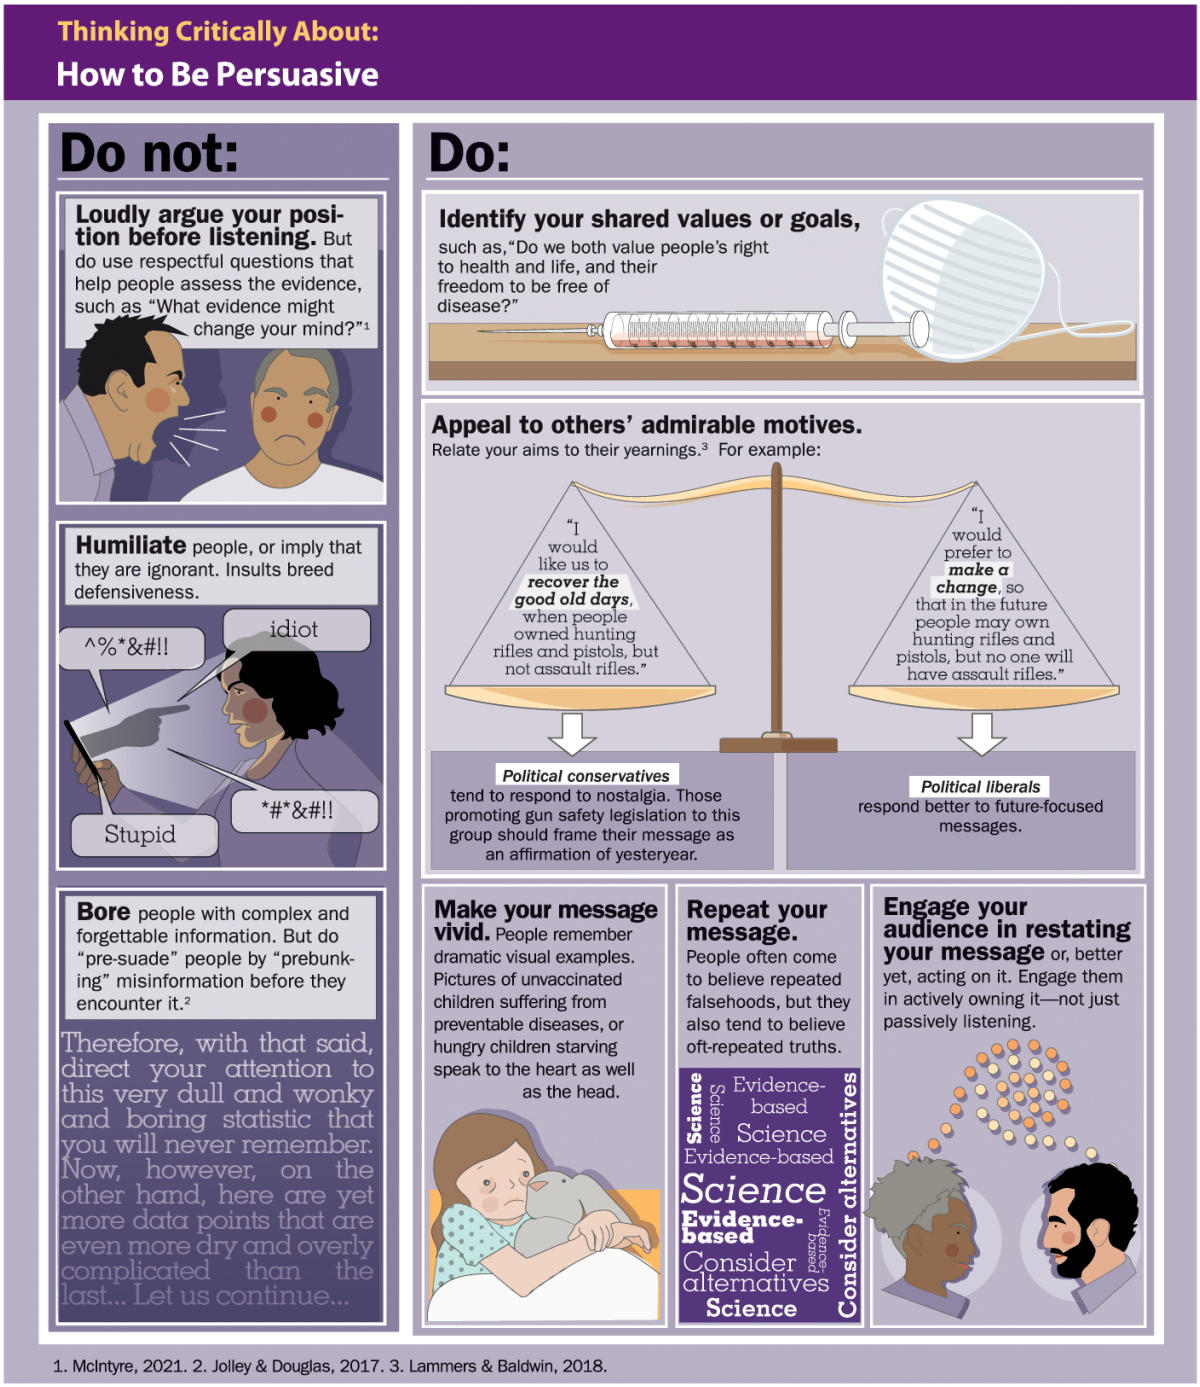
Extended description for Foot-in-the-door phenomenon

In the first panel, the teenager holds a large bag of fireworks. While his friend watches, he asks his mother, “Is it okay with you if we go up on the roof and shoot off these highly illegal fireworks?” The mother replies, “What? No!!” Her response is emphatic in all capital letters.



In the second panel, the teenager asks the mother, “Then can I stay out past my curfew to watch the public display at the park?” The mother replies, “Okay,” as she walks away holding the bag of fireworks.

In the third panel, the two teenagers are laying on blankets on the grass in a park. The first says, “Open with the outrageous, settle for your goal.” The second says, “I taught you that!”

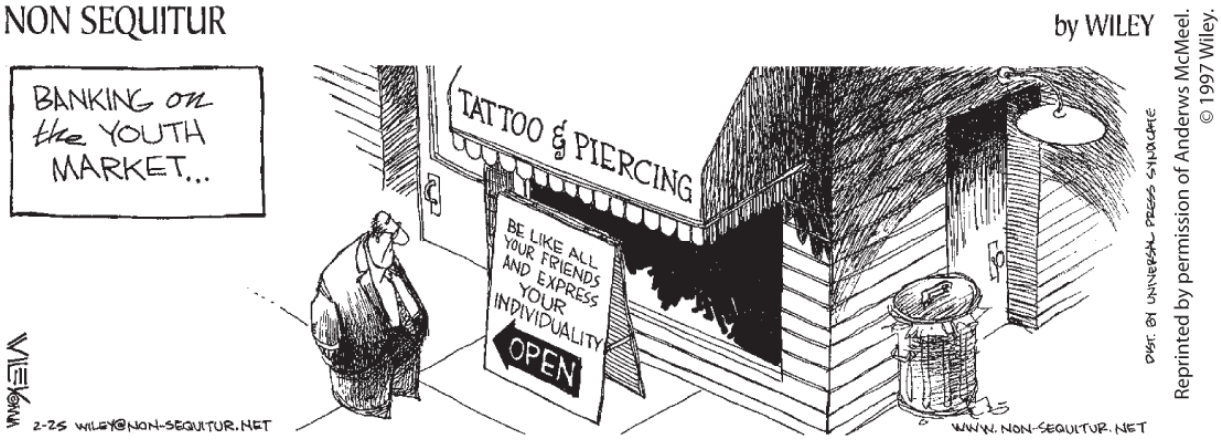
Return to Foot-in-the-door phenomenon

Extended description for How to be

persuasive

© Worth Publishers

The infographic lists things to do and things not to do in two sections. The section on the left, titled **Do not**, shows three panels.



Panel 1: **Loudly argue your position before listening**. But do use respectful questions that help people assess the evidence, such as, "what evidence might change your mind?" (McIntyre, 2021). A cartoon shows an angry man yelling loudly into the face of another person, whose cheeks are read with anger. Panel 2: **Humiliate** people, or imply that they are ignorant. Insults breed defensiveness. A cartoon shows a woman checking a text on her phone with several texts communicated. One says stupid, the other says idiot, and two text boxes have symbols that indicate profanity. The woman has red cheeks from anger. Panel 3: **Bore** people with complex and forgettable information. But do "pre-suade" people by "prebunking" misinformation before they encounter it (Jolley and Douglas, 2017). As an example of useless information, Text reads, therefore with that said, direct your attention to this very dull and wonky and boring statistic that you will never remember. Now, however, on the other hand, here are yet more data points that are even more dry and overly complicated than the last…. Let us continue….

The section on the right, titled **Do,** shows five panels. Panel 1: **Identify your shared values or goals**, such as, "Do we both value people's right to health and life, and their freedom to be free of disease?" An illustration of a protective mask and a hypodermic needle appears beneath the text. Panel 2: **Appeal to others' admirable motives**. Relate your aims to their yearnings (Lammers and Baldwin, 2018). For example: A balancing scale is depicted with text on both sides that are evenly balanced. On the left side of the balance, the text reads, "I would like us to ***recover the good old days***,

when people owned hunting rifles and pistols, but not assault rifles." This text points to another text box below that reads ***Political conservatives*** tend to respond to nostalgia. Those promoting gun safety legislation to this group should frame their message as an affirmation of yesteryear. On the right side of the balance, the text reads, "I would prefer to ***make a change***, so that in the future people may own hunting rifles and pistols, but no one will have assault rifles." This text points toward another text box below that reads, ***Political liberals*** respond better to future-focused messages. Panel 3: **Make your message vivid**. People remember dramatic visual examples. Pictures of unvaccinated children suffering from preventable diseases, or hungry children starving, speak to the heart as well as the head. A cartoon shows a little girl hugging a soft toy while lying in bed under a blanket. Panel 4: **Repeat your message**. People often come to believe repeated falsehoods, but they also tend to believe oft-repeated truths. The phrases 'evidence-based science' and 'consider alternatives' are repeated below. Panel 5: **Engage your audience in restating your message** or, better yet, acting on it. Engage them in actively owning it dash not just passively listening. An illustration depicts a sequence of information being passed from one woman's brain to a man's brain.

The horizontal axis is labeled, Before discussion on the left end and After discussion on the right end. The vertical axis represents PREJUDICE and ranges from minus 4 (low) to plus 4 (high) in increments of 1. A line labeled, Low-prejudice groups starts from minus 2.2 before the discussion, and slopes downward to end at minus 3 after the discussion. A second line labeled, High-prejudice groups starts slightly below plus 3 before the discussion, and slopes upward to end at plus 3.4 after the discussion. The text reads, Discussion among like-minded people tends to strengthen preexisting attitudes.

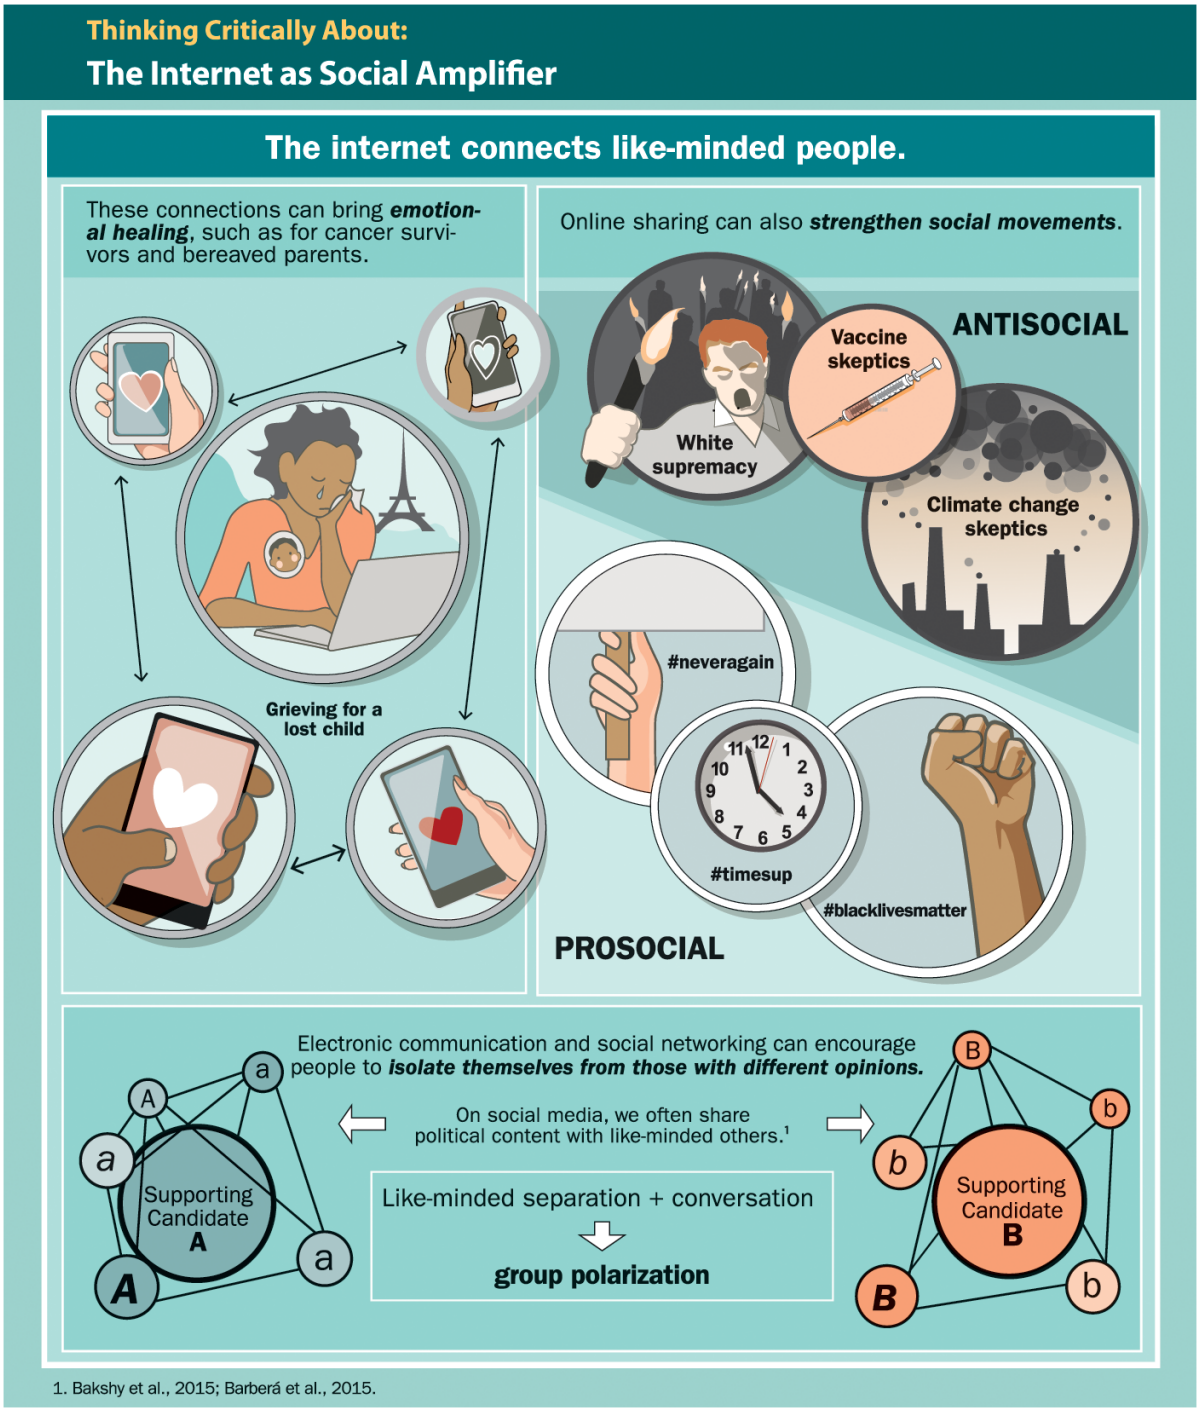
Extended description for Technology’s a

mixed bag

Technology is a Mixed Bag by Andy Singer/Cagle Cartoons, Inc.



In the first panel, the boy has his hand raised, elbow bent, as he gesticulates a victory sign. He says, Social media helps me connect with other gay and bisexual kids and feel less isolated in my small town.

In the second panel, the boy has his hand raised with fingers fully stretched upward. He says, Social media helps me connect with Nazis and White supremacists and feel less isolated in my small town.

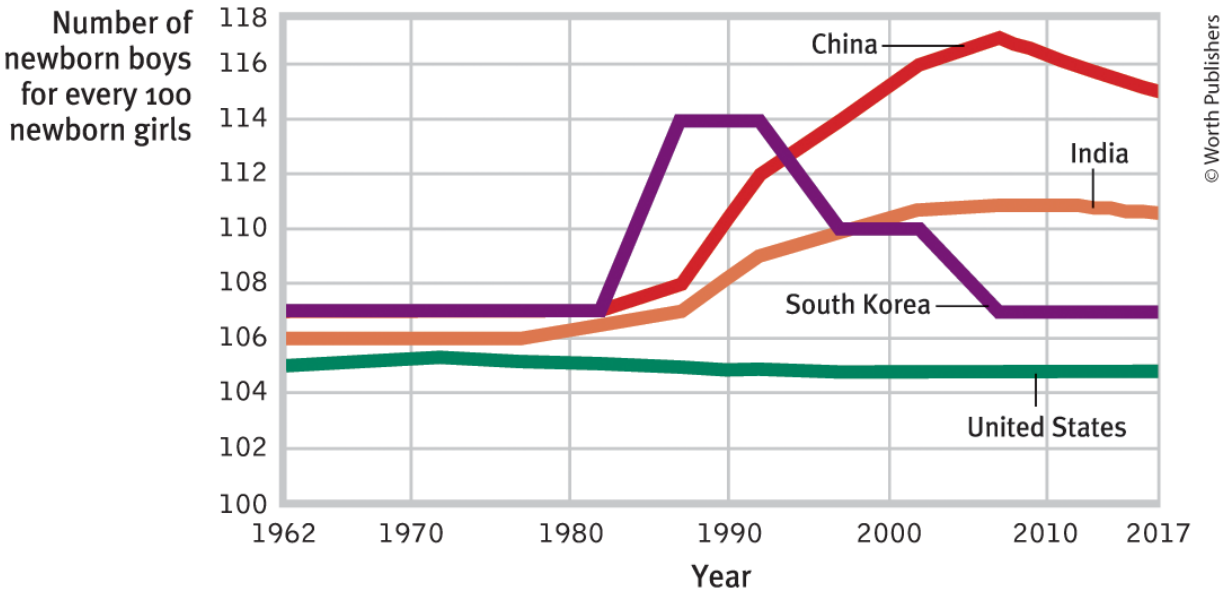
Return to Technology's a mixed bag

Extended description for Internet as social

amplifier

© Worth Publishers

The header reads, **The internet connects like-minded people.** The infographic shows three sections. The first section shows the text, These connections can bring ***emotional healing***, such as for cancer survivors and bereaved parents. The illustration has a large circle with four smaller circles surrounding it. The large circle shows a woman looking at her laptop, crying. Behind her is the Eiffel Tower, and she is wearing a pin with the face of a young boy on it. The caption under the woman reads, Grieving for a lost child. In the smaller circles around her are images of phone screens with heart symbols. There are double arrows between all the circles, indicating interconnectedness.



The second section shows the text, Online sharing can also ***strengthen social movements***. There are six circles arranged in a circle. Three circles have dark colors, and three circles have light colors. The three dark circles have the label, **ANTISOCIAL**. Inside the first circle is an illustration of an angry White man brandishing a lit torch, with dark silhouettes of other people holding torches behind him. The label in the circle is White supremacy. Inside the second circle is an illustration of a hypodermic needle. The label in the circle is Vaccine skeptics. Inside the third circle is an illustration of dark smokestacks spewing black clouds into an orange sky. The label in the circle is Climate change skeptics. The three light circles have the label **PROSOCIAL**. Inside the first circle is an illustration of a woman's hand holding up a sign. The label in the circle is hashtag never again. Inside the second circle is an illustration of a Black

person's raised, clenched fist. The label in the circle is hashtag Black Lives Matter. Inside the third circle is an illustration of a clock with the hour hand at five and the minute hand almost to twelve. The label in the circle is hashtag Time's Up.

The third section shows the text, Electronic communication and social networking can encourage people to ***isolate themselves from those with different opinions***. Under this are two illustrations with a textbox in the middle. The text reads, On social media, we often share political content with like-minded others (Bakshy et al., 2015; Barberá et al., 2015). On the left of this text is a left-facing arrow. It points to a large circle surrounded by five smaller circles. The text in the large circle reads, Candidate **A**. The text in the smaller circles has the letter a. The small circles around the large circle are all connected by lines to each other, and two are connected to the center circle. On the right of the text is a right-facing arrow. It points to the same arrangement of circles, but the text in these circles is Candidate **B** in the large circle and the letter b in the smaller circles. The connecting lines are the same. The lines in these illustrations create a closed system and show how Candidates A and B and their supporters isolate themselves. A text box below these illustrations reads, Like-minded separation plus conversation leads to **group polarization**.

Extended description for FIGURE 45.1 Freud's idea of the mind's structure

© Worth Publishers

The part of the iceberg above the water line is labeled ***Conscious mind***. The area immediately below the water but close to the surface is labeled, ***Preconscious mind*** *(outside awareness but accessible)*. The area at the bottom of the iceberg that is deeply submerged is labeled

Unconscious mind. The conscious and preconscious parts of the iceberg are each split into two halves, the ego and the superego. The **Ego** is mostly conscious; makes peace between the i d and the superego. The **Superego** is internalized ideas. Contained entirely in the unconscious mind is the **I d**, which is labeled unconscious energy.

Extended description for FIGURE 46.1 Characteristics of Self-Actualization Scale (C S A S)

© Worth Publishers

Characteristics of Self-Actualization Scale (CSAS)

Here are a number of characteristics that may or may not describe you. Please select the answer that best indicates the extent to which you agree or disagree with each statement. Be as honest as possible, but rely on your initial feeling and do not think too much.

1	2	3	4	5
Strongly disagree	**Disagree**	**Neutral**	**Agree**	**Strongly agree**

1. ___I often feel gratitude for the good in my life no matter how many times I encounter it.
2. ___I accept all sides of myself, including my shortcomings.
3. ___I take responsibility for my actions.
4. ___I am often undisturbed and unruffled by things that seem to bother most people.
5. ___I have a purpose in life that will help the good of humankind.
6. ___I often have a clear perception of reality.
7. ___I have a genuine desire to help the human race.
8. ___I often have experiences in which I feel one with all people and things on this planet.
9. ___I have a strong sense of right and wrong in my daily life.
10. ___I bring a generally creative attitude to all of my work.

Scoring Guide:
Add up your scores and divide by 10 for your total score. The items above represent the 10 characteristics of self-actualization studied by Scott Barry Kaufman (2018):
(1) Continued freshness of appreciation, (2) Acceptance, (3) Authenticity, (4) Equanimity (mental calmness), (5) Purpose, (6) Truth seeking, (7) Humanitarianism (concern with human welfare), (8) Peak experiences, (9) Good moral intuition, and (10) Creative spirit.

Kaufman found that those with higher scores experienced "greater life satisfaction, self-acceptance, positive relations, personal growth, purpose in life, and self-transcendent experiences" as well as "creativity across multiple domains of achievement."

Information from Kaufman (2018)

The survey is titled, Characteristics of Self-Actualization Scale (C S A S). Text reads as follows: Here are a number of characteristics that may or may not describe you. Please select the number that best indicates the extent to which you agree or disagree with each statement. Be as honest as possible, but rely on your internal feelings and do not think too much.

Under this is a scale from 1 (left) to 5 (right) that reads: **1, strongly disagree; 2, disagree; 3, neutral; 4, agree; and 5, strongly agree.**

Ten statements come next, as follows:

1. I often feel gratitude for the good in my life no matter how many times I encounter it.

2. I accept all sides of myself, including my shortcomings.

3. I take responsibility for my actions.

4. I am often undisturbed and unruffled by things that seem to bother most people.

5. I have a purpose in life that will help the good of humankind.

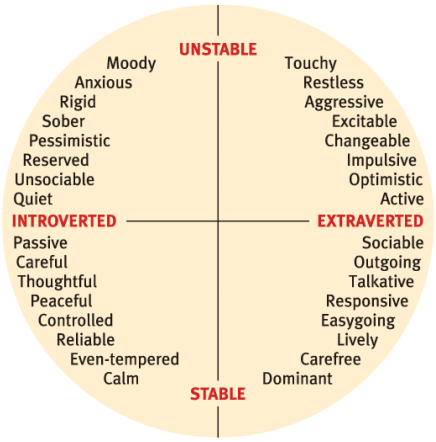
6. I often have a clear perception of reality.

7. I have a genuine desire to help the human race.

8. I often have experiences in which I feel one with all people and things on this planet.

9. I have a strong sense of right and wrong in my daily life.

10. I bring a generally creative attitude to all of my work.

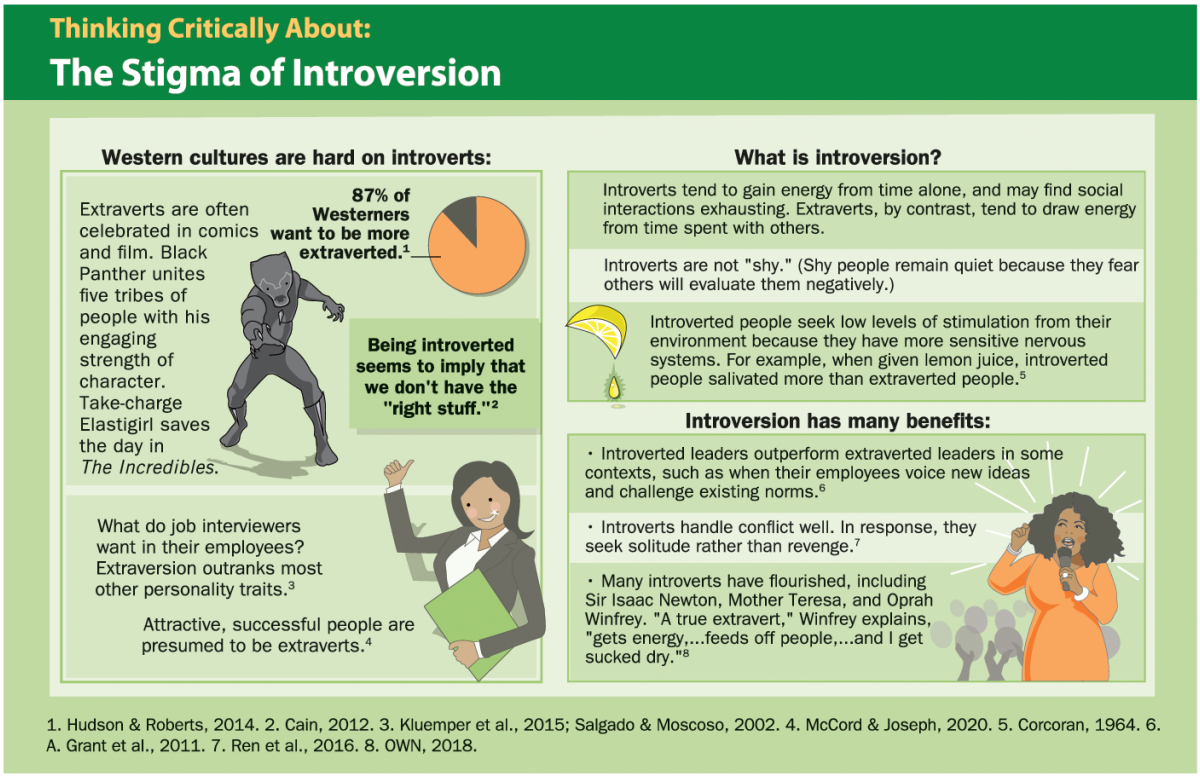


A **Scoring Guide** appears next: Add up your scores and divide by 10 for your total score. The items above represent the 10 characteristics of self-actualization studied by Scott Barry Kaufman (2018): (1) continued freshness of appreciation, (2) acceptance, (3) authenticity, (4) equanimity (mental calmness), (5) purpose, (6) truth seeking, (7) humanitarianism (concern for human welfare), (8) peak experiences, (9) good moral intuition, and (10) creative spirit.

Kaufman found that those with higher scores experienced "greater life satisfaction, self-acceptance, positive relations, personal growth, purpose in life, and self-transcendent experiences" as well as "creativity across multiple domains of achievement."

Return to FIGURE 46.1 Characteristics of Self-Actualization Scale (C S A S)

Extended description for FIGURE 46.2 Two personality dimensions



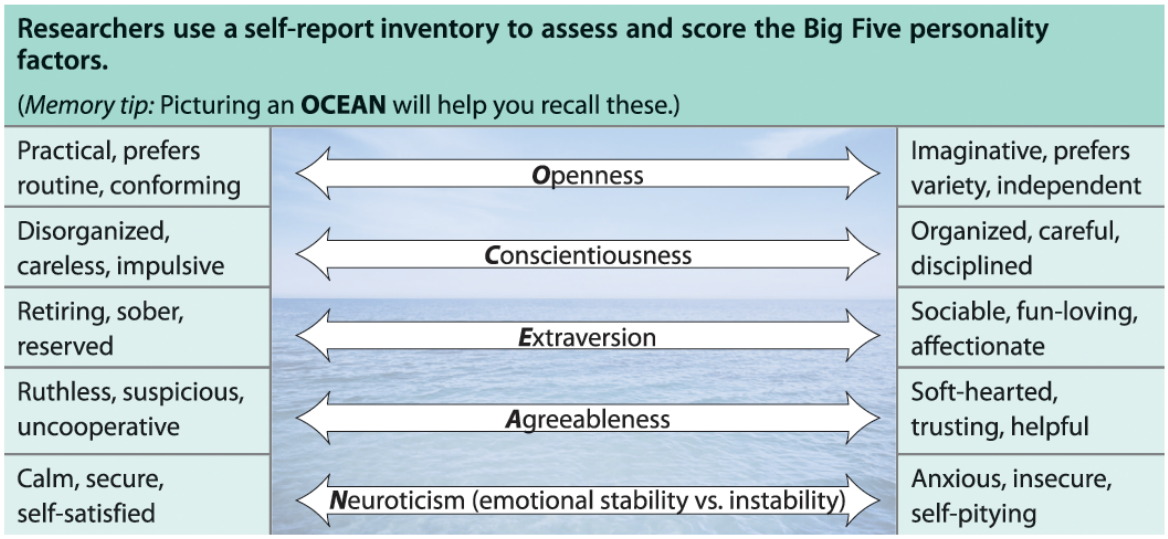
Photos left: HBO/Photofest; right: Abaca Press/Sipa/AP Photo
© Worth Publishers

The photo on the left shows actor Issa Rae, and the photo on the right shows comedian Jimmy Fallon. Issa looks quiet and calm, and Jimmy looks astonished as well as joyful. In the center is a circle with the top portion marked **UNSTABLE,** the bottom portion marked **STABLE**, the right portion marked **EXTRAVERTED**, and the left portion marked **INTROVERTED**. The traits between unstable and extraverted are Touchy, Restless, Aggressive, Excitable, Changeable, Impulsive, Optimistic, and Active. The traits between extraverted and stable are Sociable, Outstanding, Talkative, Responsive, Easygoing, Lively, Carefree, and Dominant. The traits between stable and introverted are Passive, Careful, Thoughtful, Peaceful, Controlled, Reliable, Even-tempered, and Calm. The traits between

unstable and introverted are Quiet, Unsociable, Reserved, Pessimistic, Sober, Rigid, Anxious, and Moody.

Return to FIGURE 46.2 Two personality dimensions

Extended description for Stigma of introversion



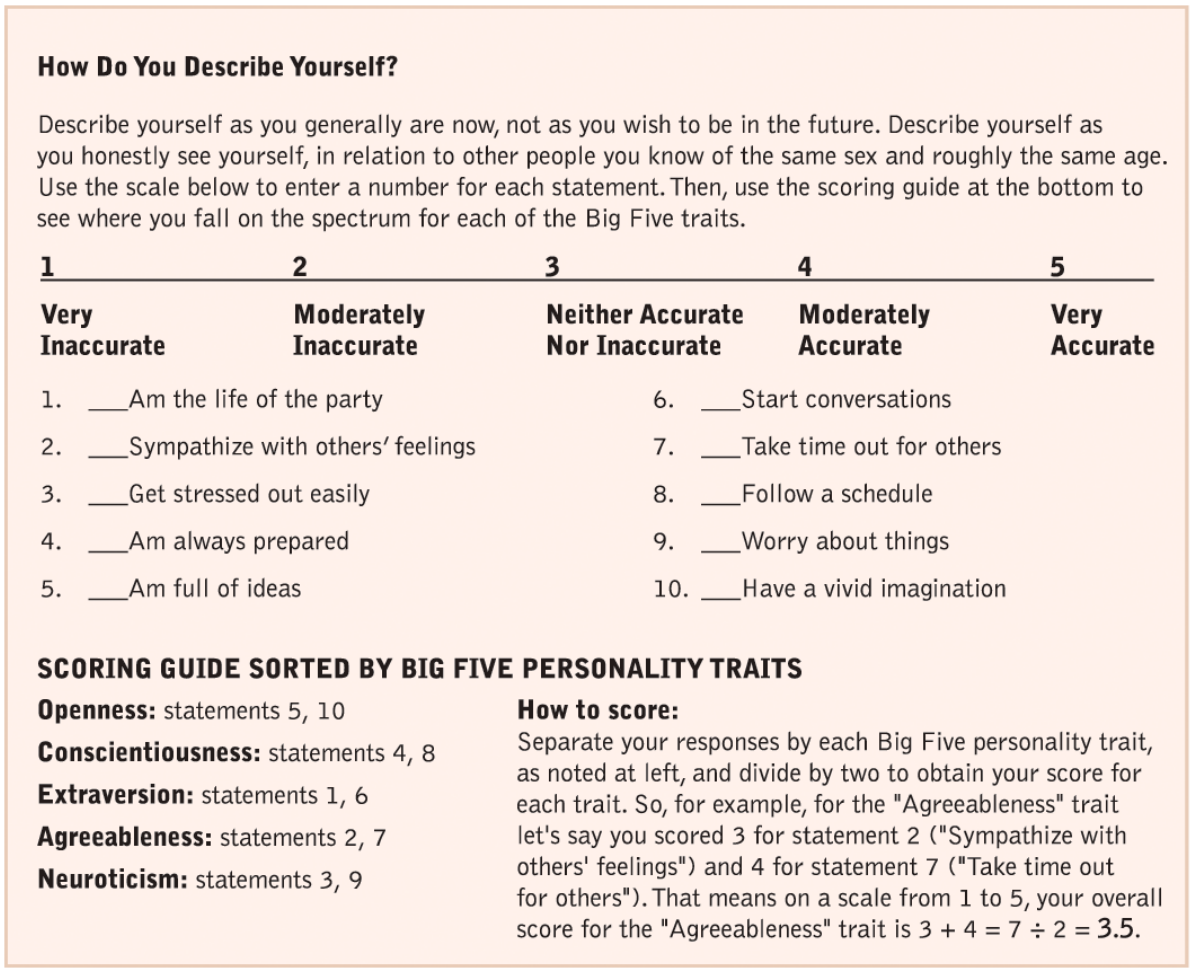
© Worth Publishers

The infographic has three sections as follows: Section 1 is titled, **Western cultures are hard on introverts:** Part 1 reads, Extraverts are often celebrated in comics and film. Black Panther unites five tribes of people with his engaging strength of character. Take-charge Elastigirl saves the day in *The Incredibles*. An illustration shows Black Panther. A pie chart is depicted that says **87 percent of Westerners want to be more extraverted** (Hudson and Roberts, 2014). **Being introverted seems to imply that we don't have the "right stuff"**

(Cain, 2012). Part 2 reads, What do job interviewers want in their employees? Extraversion outranks most other personality traits (Kluemper et al., 2015; Salgado and Moscoso, 2002). An illustration shows a woman holding a file folder and giving thumbs up. Attractive, successful people are presumed to be extraverts (McCord and Joseph, 20 20). Section 2 is titled, **What is introversion?** Part 1 reads, Introverts tend to gain energy from time alone, and may find social interactions exhausting. Extraverts, by contrast, tend to draw energy from time spent with others. Part 2 reads, Introverts are not "shy." (Shy people remain quiet because they fear others will evaluate them negatively.) Part 3 reads, Introverted people seek low levels of stimulation from their environment because they have more sensitive nervous systems. For example, when given lemon juice, introverted people salivated more than extraverted people (Corcoran, 19 64). An illustration shows a lemon wedge with a bit of juice dripping from it. Section 3 is titled, **Introversion has many benefits:** Bullet point 1 reads, Introverted leaders outperform extraverted leaders in some contexts, such as when their employees voice new ideas and challenge existing norms (A. Grant et al., 2011). Bullet point 2 reads, Introverts handle conflict well. In response, they seek solitude than revenge (Ren et al., 2016). Bullet point 3 reads, Many introverts have flourished, including Sir Isaac Newton, Mother Teresa, and Oprah Winfrey. "A true extravert," Winfrey explains, "gets energy, ellipses, feeds off people, ellipses, and I get sucked dry" (O W N, 2018).

Return to Stigma of introversion

Extended description for Big five personality factors



Aaron Foster/The Image Bank/Getty Images
© Worth Publishers

A text on the top reads: **Researchers use a self-report inventory to assess and score the Big Five personality factors.** (*Memory tip:* Picturing an **OCEAN** will help you recall these.) Below, five double-headed arrows each represent one personality factor as follows: Openness, Conscientiousness, Extraversion, Agreeableness, and Neuroticism (emotional stability versus instability). Openness: Left side reads, Practical, prefers routine, conforming; Right side reads, Imaginative, prefers variety, independent. Conscientiousness: Left side reads, Disorganized, careless, impulsive; Right side reads, Organized careful, disciplined. Extraversion: Left side reads, Retiring, sober, reserved; Right side reads, Sociable, fun-loving,

affectionate. Agreeableness: Left side reads, Ruthless, suspicious, uncooperative; Right side reads, Soft-hearted, trusting, helpful. Neuroticism (emotional stability versus instability): Left side reads, Calm, secure, self-satisfied; Right side reads, Anxious, insecure, self-pitying.

Return to Big five personality factors

Extended description for FIGURE 46.3 The Big Five self-assessment

How Do You Describe Yourself?

Describe yourself as you generally are now, not as you wish to be in the future. Describe yourself as you honestly see yourself, in relation to other people you know of the same sex and roughly the same age. Use the scale below to enter a number for each statement. Then, use the scoring guide at the bottom to see where you fall on the spectrum for each of the Big Five traits.

1	2	3	4	5
Very Inaccurate	**Moderately Inaccurate**	**Neither Accurate Nor Inaccurate**	**Moderately Accurate**	**Very Accurate**

1. ___Am the life of the party
2. ___Sympathize with others' feelings
3. ___Get stressed out easily
4. ___Am always prepared
5. ___Am full of ideas
6. ___Start conversations
7. ___Take time out for others
8. ___Follow a schedule
9. ___Worry about things
10. ___Have a vivid imagination

SCORING GUIDE SORTED BY BIG FIVE PERSONALITY TRAITS

Openness: statements 5, 10

Conscientiousness: statements 4, 8

Extraversion: statements 1, 6

Agreeableness: statements 2, 7

Neuroticism: statements 3, 9

How to score:
Separate your responses by each Big Five personality trait, as noted at left, and divide by two to obtain your score for each trait. So, for example, for the "Agreeableness" trait let's say you scored 3 for statement 2 ("Sympathize with others' feelings") and 4 for statement 7 ("Take time out for others"). That means on a scale from 1 to 5, your overall score for the "Agreeableness" trait is 3 + 4 = 7 ÷ 2 = 3.5.

© Worth Publishers

The header reads, **How Do You Describe Yourself?** Text below reads: Describe yourself as you generally are now, not as you wish to be in the future. Describe yourself as you honestly see yourself, in relation to other people you know of the same sex and roughly the same age. Use the scale below to enter a number for each statement.

Then, use the scoring guide at the bottom to see where you fall on the spectrum for each of the Big Five traits.

A scale below from 1 on left to 5 on right reads: **1, very inaccurate; 2, moderately inaccurate; 3, Neither Accurate Nor Inaccurate; 4, Moderately Accurate; and 5, Very Accurate.**

Ten statements below read as follows:

1. Am the life of the party.

2. Sympathize with others' feelings.

3. Get stressed out easily.

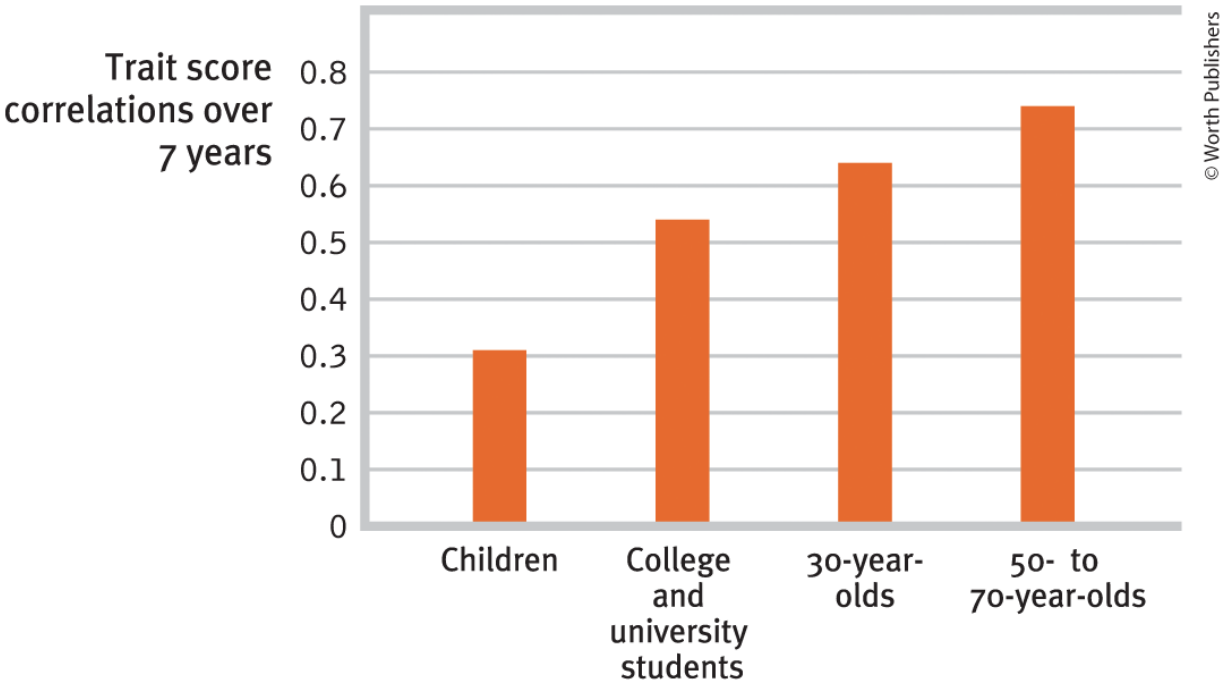
4. Am always prepared.

5. Am full of ideas.

6. Start conversations.

7. Take time out for others.

8. Follow a schedule.



9. Worry about things.

10. Have a vivid imagination.

Text below under the heading, **SCORING GUIDE SORTED BY BIG FIVE PERSONALITY TRAITS**, reads: **Openness:** statements 5, 10. **Conscientiousness:** statements 4, 8. **Extraversion:** statements 1, 6. **Agreeableness:** statements 2, 7. **Neuroticism:** statements 3, 9. The text to the right reads, **How to score:** Separate your responses by each Big Five personality trait, as noted at left, and divide by two to obtain your score for each trait. So, for example, for the "Agreeableness" trait let's say you scored 3 for statement 2 ("Sympathize with others' feelings") and 4 for statement 7 ("Take time out for others"). That means on a scale from 1 to 5, your overall score for the "Agreeableness" trait is 3 plus 4 equals 7 divided by 2 equals 3.5.

Extended description for FIGURE 48.4 Highest and lowest rates of selected

disorders worldwide

The first graph is labeled **Schizophrenia.** The horizontal axis ranges from 0 to 500, in increments of 100. The vertical axis plots bars for

different countries. The data in the graph are as follows: United States (highest), 420; United States, 420; Canada, 290; and Somalia (lowest), 190.

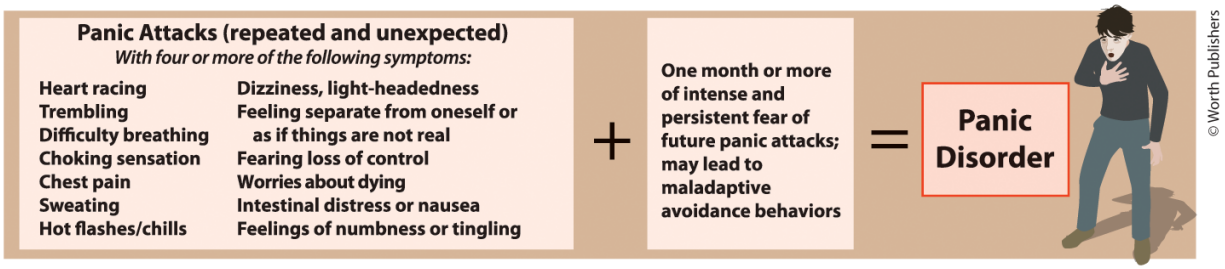
The second graph is labeled **Anorexia nervosa**. The horizontal axis ranges from 0 to 300, in increments of 50. The vertical axis plots bars for different countries. The data in the graph are as follows: Monaco (highest), 249; United States, 130; Canada, 120; and Somalia (lowest), 20.

The third graph is labeled **Major depressive disorder**. The horizontal axis ranges from 0 to 6000, in increments of 1000. The vertical axis plots bars for different countries. The data in the graph are as follows: Uganda (highest), 5300; United States, 3200; Canada, 2100; and Indonesia (lowest), 1100.

The fourth graph is labeled **Bulimia nervosa**. The horizontal axis ranges from 0 to 1000, in increments of 200. The vertical axis plots bars for different countries. The data in the graph are as follows: Australia (highest), 800; Canada, 320; United States, 300; and Somalia (lowest), 20.

The fifth graph is labeled **Bipolar disorders**. The horizontal axis ranges from 0 to 2000, in increments of 500. The vertical axis plots bars for different countries. The data in the graph are as follows: New Zealand (highest), 1500; Canada, 750; United States, 600; and China (lowest), 200.

The sixth graph is labeled **Autism spectrum disorder.** The horizontal axis ranges from 0 to 1000, in increments of 200. The vertical axis plots bars for different countries. The data in the graph are as follows: England (highest), 780; United States, 630; Canada, 600; and Taiwan (lowest), 210.

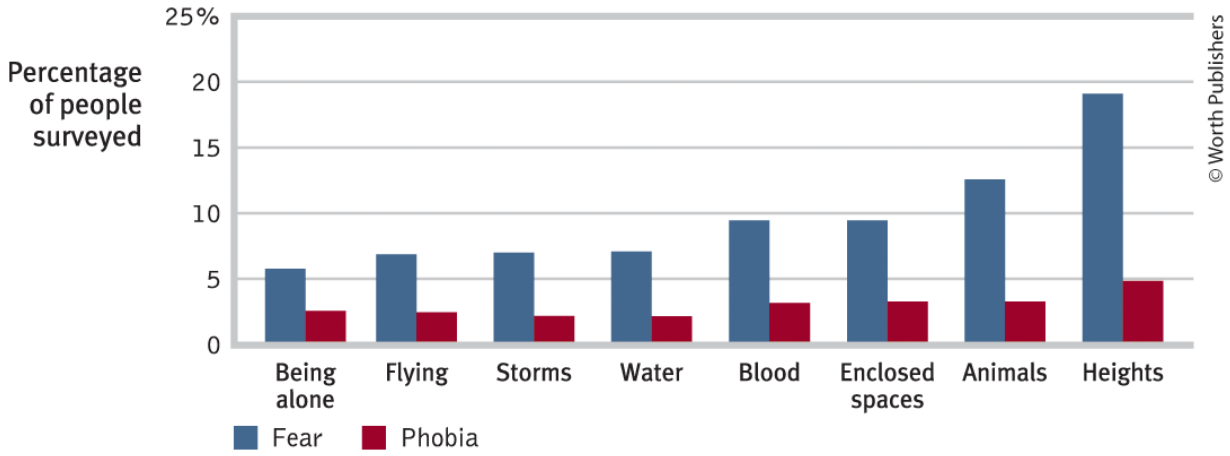


The seventh graph is labeled **Anxiety disorders**. The horizontal axis ranges from 0 to 10000, in increments of 2000. The vertical axis plots bars for different countries. The data in the graph are as follows: Portugal (highest), 8000; United States, 5800; Canada, 4200; and Kyrgyzstan (lowest), 2000.

The eighth graph is labeled **Attention-deficit slash hyperactivity disorder**. The horizontal axis ranges from 0 to 4000, in increments of 1000. The vertical axis plots bars for different countries. The data in the graph are as follows: Australia (highest) 3300; United States, 2100; Canada, 2050; and Malaysia (lowest), 500.

All data are approximate.

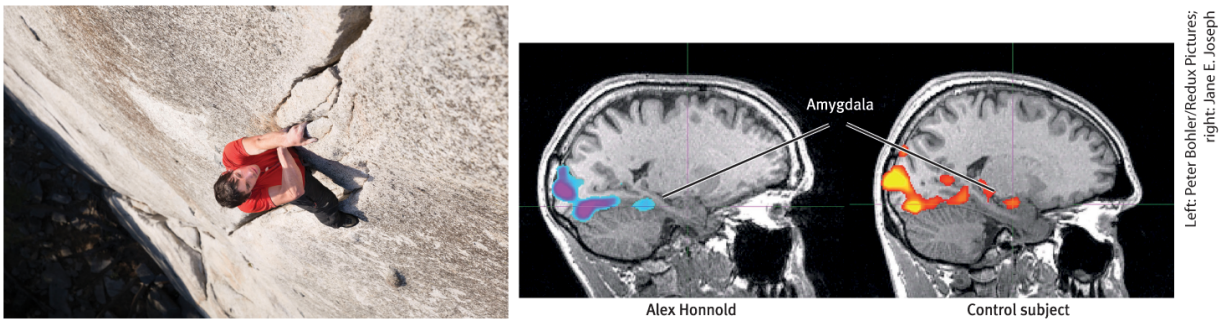
Return to FIGURE 48.4 Highest and lowest rates of selected disorders worldwide



Extended description for FIGURE 49.1 Panic disorder

The illustration is presented like a mathematical equation. The first part reads, **Panic Attack (repeated and unexpected),** *With four or more of the following symptoms:* heart racing, trembling, difficulty breathing, choking sensation, chest pain, sweating, hot flashes slash chills, dizziness, light-headedness, feeling separate from oneself or as if things are not real, fearing loss of control, worries about dying, intestinal distress or nausea, and feelings of numbness or tingling. A plus sign follows the list of symptoms. The following text appears next: One month or more of intense and persistent fear of future panic attacks; may lead to maladaptive avoidance behaviors. Then an equal sign appears, followed by the words panic disorder and an illustration of a distressed-looking person with his hand on his chest.

Return to FIGURE 49.1 Panic disorder



Extended description for FIGURE 49.2 Some common specific fears

The horizontal axis lists different events or objects that inspire fears or phobias, which are indicated by the bars on the chart. The vertical axis represents Percentage of people surveyed and ranges from 0 to 25 percent, in increments of 5. The data are as follows: Being alone: Fear 5.5 and Phobia 2.3; Flying: Fear 7 and Phobia 2.3; Storms: Fear 7 and Phobia 2.3; Water: Fear 7 and Phobia 2.3; Blood: Fear 9.5 and Phobia 3; Enclosed spaces: Fear 9.5 and Phobia 3.2; Animals: Fear 12.5 and Phobia 3.2; and Heights: Fear 19 and Phobia 5. All data are approximate.

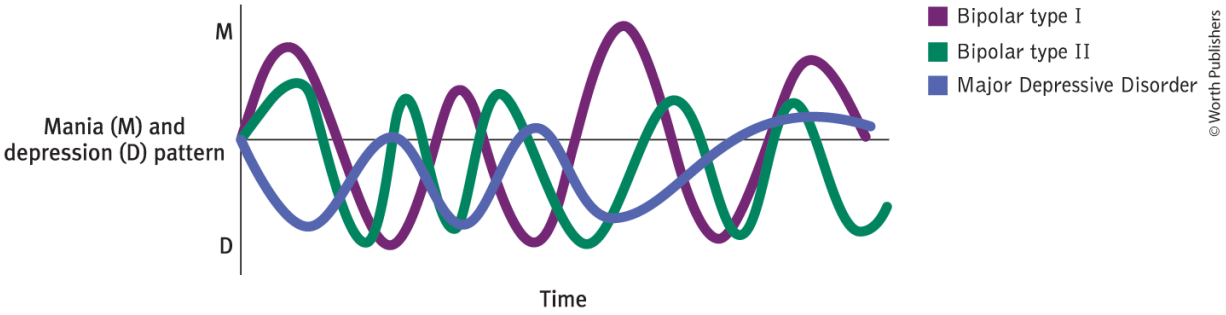
Extended description for Fearless



Left: Peter Bohler/Redux Pictures; right: Jane E. Joseph

The photo in part (a) shows an overhead view of Alex Honnold climbing a sheer rock wall without any safety ropes. Two M R I scans in part (b) show Alex Honnold's brain and a control subject's brain. In Honnold, the amygdala and nearby areas are seen in blue and purple, and in the control, the same areas are seen in orange and yellow, showing greater activation.

Return to Fearless

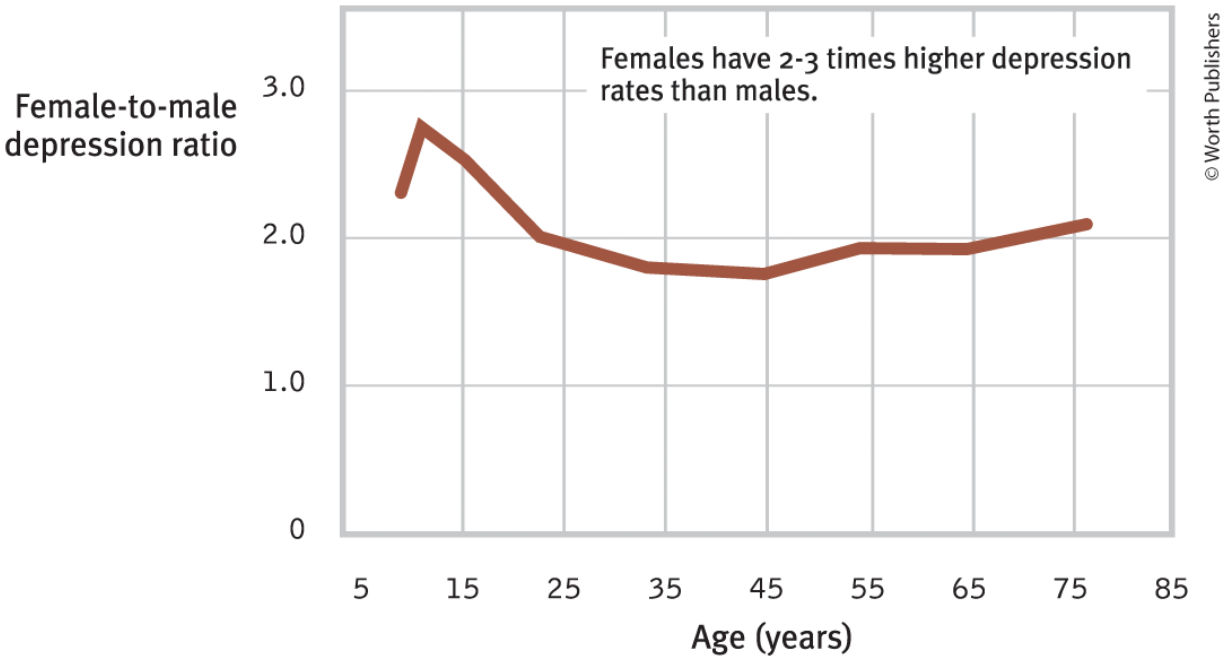
Extended description for FIGURE 50.1 Mood fluctuation in bipolar disorders, compared with major depressive disorder

A vertical line representing Mania (M) and depression (D) pattern is marked D at the bottom and M at the top. A horizontal line labeled Time begins at the center of the vertical line and extends to the right representing a steady mood. The wave-like major depressive disorder curve begins at the center of the vertical line and fluctuates below the steady mood line, in the depression (D) region. The curve ends slightly above the steady mood line on the right end. The wave-like bipolar type 1 curve begins at the center of the vertical line, rises sharply to mania, fluctuates strongly between depressive and mania regions, and ends at the steady mood line on the right end. The wave-like bipolar type 2 curve begins at the center of the vertical line, rises and drops to depression only rising slightly above the steady line in the mania region. The curve lies mostly in the

depressive state and ends well below the steady line in the depression region. All data are approximate.

Return to FIGURE 50.1 Mood fluctuation in bipolar disorders, compared with major depressive disorder

Extended description for Bipolar disorders

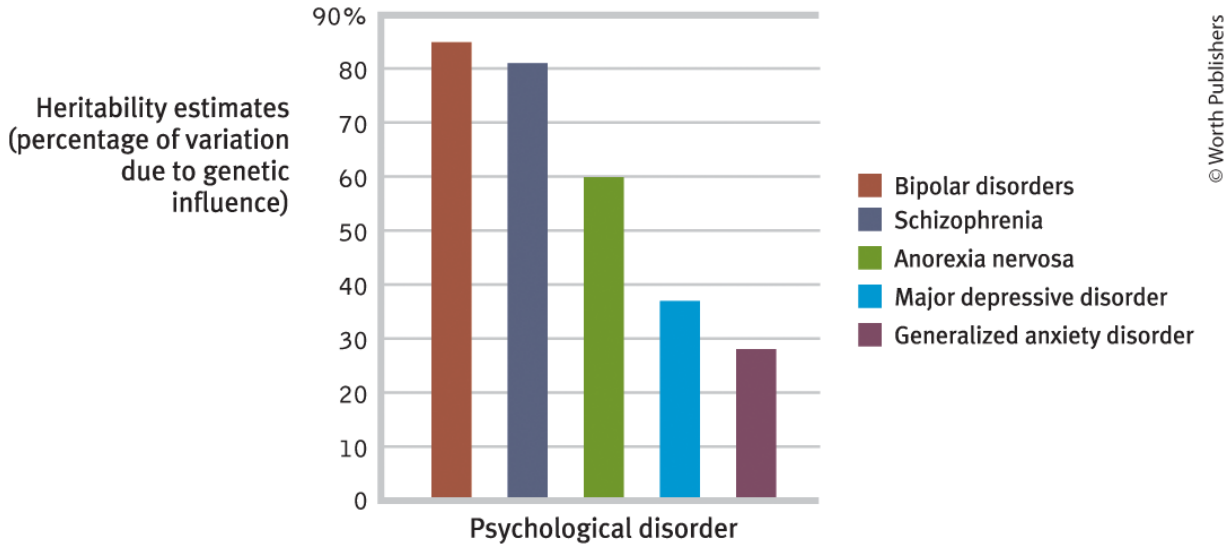


Life as a Two-Headed Beast: Bipolar, Abigail Southworth

The panting has one body and two heads, one dark and looking left and the other bright and looking right. There are several descriptive words by both heads. The head on the left has black hair, a blue and purple face, and looks downward with a despondent expression. Sentences float in the background of this half of the painting that read: Pills make you weak; Stop feeling sorry for yourself; I keep trying to help you but you don't want it; What do you have to be depressed about? and What's wrong with you? The head on the right has hair with red, purple, and blond stripes, a red and yellow face, and looks upward, with eyes and mouth opened wide in a very happy expression. Sentences float in the background of this half of the painting that read: Can't you just calm down? I don't get why you

can’t just act normal; Don’t you have pills for this? and You’re deluded. A large word showing the title of the image says BIPOLAR.

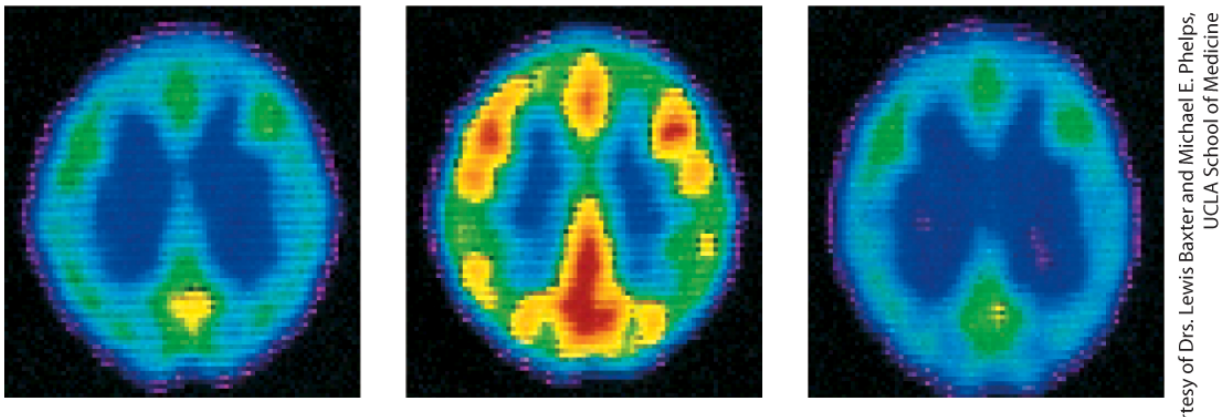
Return to Bipolar disorders



Extended description for FIGURE 50.2 Worldwide gender gap in depression

The horizontal axis represents Age (years) and ranges from 5 to 85, in increments of 10. The vertical axis represents Female-to-male depression ratio and ranges from 0 to 3.0, in increments of 1.0. The curve begins from 2.3 depression ratio at 7.5 years, rises to 2.8 depression ratio at 9 years, dips to 2.0 ratio at 25 years, then to 1.7 ratio by 45 years before climbing to end at 2.1 ratio at 77 years. All data are approximate. A text above reads, Females have 2 to 3 times higher depression rates than males.

Return to FIGURE 50.2 Worldwide gender gap in depression



Extended description for FIGURE 50.3 The heritability of various psychological disorders

The horizontal axis represents Psychological disorder. The vertical axis represents Heritability estimates (percentage of variation due to genetic influence) and ranges from 0 to 90 percent, in increments of 10 percent. The percent of each psychological disorder are as follows: Bipolar disorder, 85 percent; Schizophrenia, 81 percent; Anorexia nervosa, 60 percent; Major depressive disorder, 38 percent; and Generalized anxiety disorder, 29 percent. All data are approximate.

Extended description for FIGURE 52.1 Cold-blooded arousability and risk of crime

The horizontal axis is labeled Nonstressful situation and Stressful situation. The vertical axis represents Adrenaline excretion (nanograms per minute) and ranges from 0 to 15, in increments of 5. In nonstressful situations: No criminal conviction equals 10 and criminal convictions equals 5. In stressful situations: No criminal conviction equals 15 and criminal convictions equals 10.5. All data are approximate. Text on the top reads: Males with criminal convictions as adults had lower levels of arousal as 13-year-olds.

Return to FIGURE 52.1 Cold-blooded arousability and risk of crime

Extended description for Attention-deficit slash hyperactivity disorder

© Worth Publishers

The infographic shows six panels. The first panel has the heading, **Diagnosis in the U.S.** Under the heading are two pie charts. The one on the left is labeled, 2- to 17-year-olds, and shows that 9.4 percent of 2- to 17-year-olds have been diagnosed with A D H D (C D C, 2019 a). The second pie chart is labeled, Adults, and shows that 2.5 percent of adults have been diagnosed with A D H D (Simon et al., 2009). To the right of the pie charts text reads, Less often in many other countries such as Norway and Sweden (MacDonald et al., 2019; Smith, 2017). Below, text reads, Twice as often in BOYS as in girls, besides a large symbol for males and a small symbol for females.

The second panel has the heading, **Symptoms.** A bulleted list reads as follows: 1. Inattention and distractibility (Martel et al., 2016). 2. Hyperactivity (Kofler et al., 2016). 3. Impulsivity. Beside the bulleted list is an illustration of three children (two girls and a boy) sitting at their desks with another boy jumping all over the room, tipping the children's desks. One other boy is sitting on the floor under his desk, having been knocked out of his chair by the rambunctious boy.

The third panel is divided into two sections. On the left, the heading reads, **SKEPTICS note:** Energetic child plus boring school equals A D H D overdiagnosis. A bulleted list reads as follows: 1. Children are not meant to sit for hours in chairs inside. 2. The youngest children in a class tend to be more fidgety - and more often diagnosed (Chen, M. et al., 2016). 3. Older students may seek out stimulant A D H D prescription drugs - "good grade pills" (Schwarz, 2012). 4. We don't know the long-term effects of drug treatment. 5. There is no clear

explanation for increases in A D H D diagnoses and drugs (Ellison, 2015; Hales et al, 2018; Sayal et al., 2017). Next to the bullet list is an illustration of a pile of pills on top of a paper with the words A plus, Excellent work. On the right of this panel is the second section, where the heading reads, **SUPPORTERS note:** A bulleted list reads as follows: 1. More diagnoses reflect increased awareness. 2. "A D H D is a real neurobiological disorder whose existence should no longer be debated" (World Federation for Mental Health, 2005). 3. A D H D is associated with abnormal brain structure, abnormal brain activity patterns, and future risky or antisocial behavior (Ball et al., 2019; Hoogman et al., 2019). Under this bulleted list is an illustration of a right-facing brain.

The fourth panel has the heading, **Causes?** A bulleted list reads as follows: 1. May co-exist with a learning disorder or with defiant and temper-prone behavior. 2. May be genetic (Nikolas and Burt, 2010; Poelmans et al., 2011; Volkow et al., 2009; Williams et al., 2010). Beside this bulleted list is an illustration of a double helical of D N A.

The fifth panel has the heading, **Treatment.** To the left is an illustration of a vial of medication capsules. A bulleted list reads as follows: 1. Stimulant drugs (Ritalin and Adderall) calm hyperactivity, and increase ability to sit and focus (Barbaresi et al., 2007). So do behavior therapy and aerobic exercise (Cerrillo-Urbina et al., 2015; Pelham et al., 2016). 2. Psychological therapies help with the distress of A D H D (Fabiano et al., 2008). To the right, an illustration shows a

young woman with her head in her hands. Another woman with a clipboard is looking at her.

The sixth panel has the heading, **The bottom line:** The text reads, Extreme inattention, hyperactivity, and impulsivity can derail social, academic, and work achievements. These symptoms can be treated with medication and other therapies. But the debate continues over whether normal high energy is too often diagnosed as a psychiatric disorder, and whether there is a cost to the long-term use of stimulant drugs in treating A D H D.

1. Sánchez-Villegas et al., 2015; Marques et al., 2022; Walsh, 2011. 2. Huynh et al., 2022; MacKerron & Mourato, 2013; NEEF, 2020; Phillips, 2011. 3. Ilardi, 2009. 4. Babyak et al., 2000; Salmon, 2001; Schuch et al., 2016. 5. Irwin et al., 2022; Scott et al., 2021. 6. Bègue et al., 2018; Raine et al., 2018. 7. Ilardi, 2009, 2016.

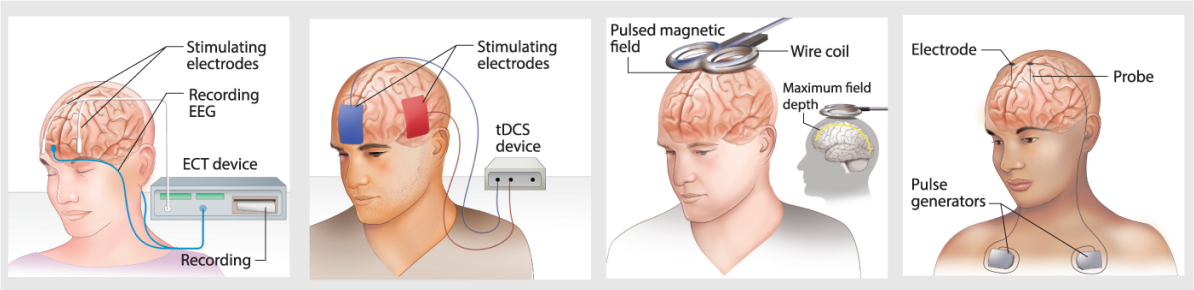
© Worth Publishers

The infographic is divided into five panels. The first panel shows a text on the left reading, **LIFESTYLE** (exercise, nutrition, relationships, recreation, service to others, relaxation, and religious or spiritual engagement). A rightward arrow points to the text, **Influences our BRAIN AND BODY**. Next, another rightward arrow points to the text, **Affects our MENTAL HEALTH** (Sánchez-Villegas et al., 2015; Walsh, 2011).

The second panel is on the left side and shows text reading, Our shared history has prepared us to be physically active and **socially engaged**. Our ancestors hunted, gathered, and built in groups. An illustration shows a group of early humans around a fire with several of them bringing wood for the fire. Below, another text reads, Modern researchers have found that outdoor activity in a natural environment reduces stress and promotes health (MacKerron and Mourato, 2013; N E E F, 2015; Phillips, 2011). An illustration shows a woman holding the hand of a little boy as they walk on a path through the trees.

To the right is the third panel with the title, **APPLICATION TO THERAPY.** Text below reads, Training seminars promote therapeutic lifestyle change (Ilardi, 2009). Small groups of people with depression undergo a 12-week training program with the following goals: Text box 1: **Aerobic exercise,** 30 minutes a day, at least three times weekly (increases fitness and vitality, stimulates endorphins). An accompanying illustration shows a person with his head turned to left, looking at a basketball in his hand. On the other side of the

person is the text reading, Regular aerobic exercise rivals the healing power of antidepressant drugs (Babyak et al., 2000; Salmon, 2001; Schuch et al., 2016). The same illustration shows the same man's head turned to right, looking at a bottle of pills in his hand. Text box 2: **Light exposure**, 15 to 30 minutes each morning with a light box (amplifies arousal, influences hormones). An accompanying illustration shows a beaming light source with different rings of light intensity. Text box 3: **Reducing rumination**, by identifying and redirecting negative thoughts (enhances positive thinking). An accompanying illustration shows a woman with a thought bubble of herself as a smiling, happy child. Text box 4: **Adequate sleep**, with a goal of 7 to 8 hours per night. An arrow points down to text reading: A complete night's sleep boosts immunity and increases energy, alertness, and mood (Gregory et al., 2009; Walker and van der Helm, 2009). An accompanying illustration shows a young man sleeping with a line of Zs coming out of his mouth. Text box 5: **Social connection**, with less alone time and at least two meaningful social engagements weekly (helps satisfy the human need to belong). An accompanying illustration shows three people dancing under a disco ball. Text box 6: **Nutritional supplements**, including a daily supplement with omega-3 fatty acids (reduces aggressive behavior) (Begue et al., 2017; Raine et al., 2018).



Below, a fourth panel is titled, **Initial small study (74 participants)** (Ilardi, 2009, 2016). Under the heading are two pie charts. The chart on the left shows that 77 percent of those who completed the program experienced relief from depressive symptoms. The chart

on the right shows that only 19 percent of those assigned to a treatment as usual control group showed similar results. Under these pie charts, a text reads: Future research will try to identify which parts of the treatment produce the therapeutic effect.

The fifth panel at the bottom has text that reads, **The biomedical therapies assume that mind and body are a unit: Affect one and you will affect the other.** An illustration shows a seated young man leaning against a wall. There are arrows pointing from his head to his body and from his body to his head.

Return to Therapeutic lifestyle change

Extended description for FIGURE 56.1 A stimulating experience

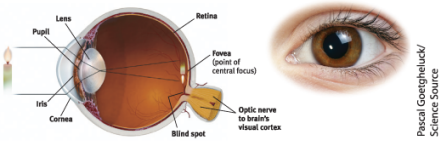
Extended description for History of psychology



B.C.E.

387— Plato, who believed in innate ideas, suggests that the brain is the seat of mental processes.

335— Aristotle, who denied the existence of innate ideas, suggests that the heart is the seat of mental processes.

C.E.

1604— Johannes Kepler describes the inverted image on the retina.

Pascal Goetgheluck/ Science Source

Inverted image on the retina

1605— Francis Bacon publishes *The Proficiency and Advancement of Learning*.

1637— René Descartes, the French philosopher and mathematician who proposed mind–body interaction and the doctrine of innate ideas, publishes *A Discourse on Method*.

1690— John Locke, the British philosopher who rejected Descartes' notion of innate ideas and insisted that the mind at birth is a "blank slate" *(tabula rasa)*, publishes *An Essay Concerning Human Understanding*, which stresses empiricism over speculation.

1774— Franz Mesmer, an Austrian physician, performs his first supposed cure using "animal magnetism" (later called mesmerism and hypnosis). In **1777,** he was expelled from the practice of medicine in Vienna.

1793— Philippe Pinel releases the first psychiatric patients from their chains at the Bicêtre Asylum in France and advocates for more humane treatment of psychiatric patients.

1802— Thomas Young publishes *A Theory of Color Vision* in England. (His theory was later called the trichromatic theory.)

1808— Franz Joseph Gall, a German physician, describes phrenology, the false belief that the shape of a person's skull reveals mental faculties and character traits.

1813— The first private psychiatric hospital in the United States opens in Philadelphia.

1834— Ernst Heinrich Weber publishes *The Sense of Touch*, in which he discusses the "just noticeable difference (jnd)" and what we now call Weber's law.

1840— 

Dorothea Dix begins advocating for humane treatment of people in mental health institutions, persuading politicians to construct psychiatric hospitals.

Dorothea Dix (1802–1887)

All Portraits: Macmillan Learning

1844— In Philadelphia, 13 superintendents form the *Association of Medical Superintendents of American Institutions for the Insane* (now known as the American Psychiatric Association).

1848— Phineas Gage suffers massive brain damage when a large iron rod accidentally pierces his brain, leaving his intellect and memory intact but altering his personality.

Warren Anatomical Museum in the Francis A. Countway Library of Medicine. Gift of Jack and Beverly Wilgus.

Phineas Gage

1850— Hermann von Helmholtz measures the speed of the nerve impulse.

1859— Charles Darwin publishes *On the Origin of Species by Means of Natural Selection*, synthesizing much previous work on the theory of evolution, including that of Herbert Spencer, who coined the phrase "survival of the fittest."

1861— Paul Broca, a French physician, discovers an area in the left frontal lobe of the brain (now called Broca's area) that is critical for the production of spoken language.

1869— Francis Galton, Charles Darwin's cousin, publishes *Hereditary Genius*, in which he claims that intelligence is inherited. In **1876,** he coins the expression "nature and nurture" to correspond with "heredity and environment." Later, Galton proposes harmful ideas about how to improve the genetic quality of human populations (called *eugenics*) that would inform prejudiced and discriminatory policies.

1874— Carl Wernicke, a German neurologist and psychiatrist, shows that damage to a specific area in the left temporal lobe (now called Wernicke's area) disrupts ability to comprehend or produce spoken or written language.

1878— G. Stanley Hall receives from Harvard University's Department of Philosophy the first U.S. Ph.D. degree based on psychological research.

The timeline presents the following events:

B.C.E.

387: Plato, who believed in innate ideas, suggests that the brain is the seat of mental processes.

335: Aristotle, who denied the existence of innate ideas, suggests that the heart is the seat of mental processes.

C.E.

16 04: Johannes Kepler describes inverted image on the retina. A schematic shows the anatomy of eye with a photo of the same. The schematic has the following parts labeled: Lens, Pupil, Iris, Cornea, Retina, Fovea (point of central focus), optic nerve to brain's visual cortex, and the blind spot.

16 05: Francis Bacon publishes *The Proficiency and Advancement of Learning*.

16 37: René Descartes, the French philosopher and mathematician who proposed mind–body interaction and the doctrine of innate ideas, publishes *A Discourse on Method*.

16 90: John Locke, the British philosopher who rejected Descartes' notion of innate ideas and insisted that the mind at birth is a "blank slate" (tabula rasa), publishes *An Essay Concerning Human Understanding*, which stresses empiricism over speculation.

17 74: Franz Mesmer, an Austrian physician, performs his first supposed cure using "animal magnetism" (later called mesmerism and hypnosis). In **17 77** he was expelled from the practice of medicine in Vienna.

17 93: Philippe Pinel releases the first mental patients from their chains at the Bicêtre Asylum in France and advocates for more humane treatment of psychiatric patients.

18 02: Thomas Young publishes *A Theory of Color Vision* in England. (His theory was later called the trichromatic theory.)

18 08: Franz Joseph Gall, a German physician, describes phrenology, the false belief that the shape of a person's skull reveals mental faculties and character traits.

18 13: The first private psychiatric hospital in the United States opens in Philadelphia.

18 34: Ernst Heinrich Weber publishes *The Sense of Touch*, in which he discusses the "just noticeable difference (jnd)" and what we now call Weber's law.

18 40: Dorothea Dix begins advocating for humane treatment of people in mental institutions, persuading politicians to construct psychiatric hospitals. A portrait shows Doreatha Dix (18 02 to 18 87).

18 44: In Philadelphia, 13 superintendents form *The Association of Medical Superintendents of American Institutions for the Insane* (now known as the American Psychiatric Association).

18 48: Phineas Gage suffers massive brain damage when a large iron rod accidentally pierces his brain, leaving his intellect and memory intact but altering his personality. An illustration shows an iron rod piercing through a human skull from down along with a black-and-white photo of Phineas Gage.

18 50: Hermann von Helmholtz measures the speed of the nerve impulse.

18 59: Charles Darwin publishes *On the Origin of Species by Means of Natural Selection*, synthesizing much previous work on the theory of evolution, including that of Herbert Spencer, who coined the phrase "survival of the fittest."

18 61: Paul Broca, a French physician, discovers an area in the left frontal lobe of the brain (now called Broca's area) that is critical for the production of spoken language.

18 69: Francis Galton, Charles Darwin's cousin, publishes *Hereditary Genius*, in which he claims that intelligence is inherited. In 1876 he coins the expression "nature and nurture" to correspond with "heredity and environment." Later, Galton proposes harmful ideas

about how to improve the genetic quality of human populations (called *eugenics*) that would inform prejudiced and discriminatory policies.

18 74: Carl Wernicke, a German neurologist and psychiatrist, shows that damage to a specific area in the left temporal lobe (now called Wernicke's area) disrupts ability to comprehend or produce spoken or written language.

18 78: G. Stanley Hall receives from Harvard University's Department of Philosophy the first U S P h D degree based on psychological research.

Return to History of psychology

Extended description for History of

psychology

1879 
Wilhelm Wundt establishes at the University of Leipzig, Germany, the first psychology laboratory, which becomes a mecca for psychology students from all over the world.

Wilhelm Wundt (1832–1920)

1883 G. Stanley Hall, student of Wilhelm Wundt, establishes the first formal U.S. psychology laboratory at Johns Hopkins University.

1885 Hermann Ebbinghaus publishes *On Memory,* summarizing his extensive research on learning and memory, including the "forgetting curve."

1886 Joseph Jastrow receives from Johns Hopkins University the first Ph.D. degree awarded by a U.S. Department of Psychology.

1889 
Henri-Étienne Beaunis and Alfred Binet establish France's first psychology laboratory at the Sorbonne.

Alfred Binet (1857–1911)

The first International Congress of Psychology meets in Paris.

1890 
William James, Harvard University philosopher and psychologist, publishes *The Principles of Psychology,* describing psychology as "the science of mental life."

William James (1842–1910)

1891 James Mark Baldwin establishes the first psychology laboratory in the British Commonwealth at the University of Toronto.

1892 G. Stanley Hall spearheads the founding of the American Psychological Association (APA) and becomes its first president.

1893 

Mary Whiton Calkins and Christine Ladd-Franklin are the first women elected to membership in the APA.

Mary Whiton Calkins (1863–1930)

Christine Ladd-Franklin (1847–1930)

1894 Margaret Floy Washburn is the first woman to receive a Ph.D. degree in psychology (Cornell University).

Harvard University denies Mary Whiton Calkins admission to doctoral candidacy because of her gender. She goes on to publish more than 100 scientific articles related to memory and the self.

1896 John Dewey publishes "The Reflex Arc Concept in Psychology," helping to formalize the school of psychology called functionalism.

1898 In *Animal Intelligence,* Edward L. Thorndike describes his learning experiments with cats in "puzzle boxes." In **1905,** he proposes the "law of effect."

Doctoral student Alice Lee uses published data from the *Journal of Anatomy* to debunk the popular phrenology and eugenics arguments that skull size predicts intelligence.

1900 Sigmund Freud publishes *The Interpretation of Dreams,* his major theoretical work on psychoanalysis.

1901 Ten founders establish the British Psychological Society.

1904 Ivan Pavlov is awarded the Nobel Prize for Physiology or Medicine for his studies on the physiology of digestion.

1905 Mary Whiton Calkins becomes the first woman president of the APA.

Ivan Pavlov begins publishing studies of conditioning in animals.

Ivan Pavlov (1849–1936)

Alfred Binet and Théodore Simon produce the first intelligence test for assessing the abilities and academic progress of Parisian schoolchildren.

1909 
Sigmund Freud makes his only trip to America to deliver a series of lectures at Clark University.

Sigmund Freud (1856–1939)

1913 
John B. Watson outlines the tenets of behaviorism in a *Psychological Review* article, "Psychology as the Behaviorist Views It."

John Watson (1878–1958)

1914 Lilian Gilbreth publishes *Principles of Management,* a foundational text for the field of industrial-organizational psychology.

During World War I, Robert Yerkes and his staff develop a group intelligence test for evaluating U.S. military personnel, which increases the U.S. public's acceptance of psychological testing.

All Portraits: Macmillan Learning

The timeline presents the following events:

18 79: Wilhelm Wundt establishes at the University of Leipzig, Germany, the first psychology laboratory, which becomes a mecca for psychology students from all over the world. A portrait shows Wilhelm Wundt (18 32 to 19 20).

18 83: G. Stanley Hall, student of Wilhelm Wundt, establishes the first formal U S psychology laboratory at Johns Hopkins University.

18 85: Hermann Ebbinghaus publishes *On Memory*, summarizing his extensive research on learning and memory, including the "forgetting curve."

18 86: Joseph Jastrow receives from Johns Hopkins University the first P h D degree in psychology awarded by a U S Department of Psychology.

18 89: Henri-Étienne Beaunis and Alfred Binet establish the first psychology laboratory in France at the Sorbonne; and the first International Congress of Psychology meets in Paris. A portrait shows Alfred Binet (18 57 to 19 11).

18 90: William James, Harvard University philosopher and psychologist, publishes *The Principles of Psychology*, describing psychology as "the science of mental life." A portrait shows William James (18 42 to 19 10).

18 91: James Mark Baldwin establishes the first psychology laboratory in the British Commonwealth at the University of Toronto.

18 92: G. Stanley Hall spearheads the founding of the American Psychological Association (A P A) and becomes its first president.

18 93: Mary Whiton Calkins and Christine Ladd-Franklin are the first women elected to membership in the A P A. Two portraits show Mary Whiton Calkins (18 63 to 19 30) and Christine Ladd-Franklin (18 47 to 19 30).

18 94: Margaret Floy Washburn is the first woman to receive a P h D degree in psychology (Cornell University). Harvard University denies Mary Whiton Calkins admission to doctoral candidacy because of her gender. She goes on to publish more than 100 scientific articles related to memory and the self.

18 96: John Dewey publishes “The Reflex Arc Concept in Psychology,” helping to formalize the school of psychology called functionalism.

18 98: In *Animal Intelligence,* Edward L. Thorndike, Columbia University, describes his learning experiments with cats in “puzzle boxes.” In 1905, he proposes the “law of effect.” Doctoral student Alice Lee uses published data from the *Journal of Anatomy* to debunk

the popular eugenics argument that skull size is related to intelligence.

1900: Sigmund Freud publishes *The Interpretation of Dreams*, his major theoretical work on psychoanalysis.

19 01: Ten founders establish the British Psychological Society.

19 04: Ivan Pavlov is awarded the Nobel Prize for Physiology or Medicine for his studies on the physiology of digestion.

19 05: Mary Whiton Calkins becomes the first woman president of the A P A. Ivan Pavlov begins publishing studies of conditioning in animals. A portrait shows Ivan Pavlov (18 49 to 19 36). Alfred Binet and Théodore Simon produce the first intelligence test for assessing the abilities and academic progress of Parisian schoolchildren.

19 09: Sigmund Freud makes his only trip to America to deliver a series of lectures at Clark University. A portrait shows Sigmund Freud (18 56 to 19 39).

19 13: John B. Watson outlines the tenets of behaviourism in a *Psychological Review* article, “Psychology as the Behaviorist Views It.” A portrait shows John Watson (18 78 to 19 58).

19 14: Lilian Gilbreth publishes *Principles of Management*, a foundational text for the field of industrial-organizational

psychology. During World War 1, Robert Yerkes and his staff develop a group intelligence test for evaluating U S military personnel, which increases the U S public's acceptance of psychological testing.

Return to History of psychology

Extended description for History of psychology

1920 — 

Leta Stetter Hollingworth publishes *The Psychology of Subnormal Children,* an early classic. In **1921,** she is cited in *American Men of Science* for her research on the psychology of women.

Leta Stetter Hollingworth
(1886–1939)

Francis Cecil Sumner becomes the first Black person in the U.S. to receive a Ph.D. degree in psychology (Clark University). He later co-founds the psychology department at Howard University.

Francis Cecil Sumner
(1895–1954)

John B. Watson and Rosalie Rayner report conditioning a fear reaction in a child called "Little Albert."

1921 — Hermann Rorschach, a Swiss psychiatrist, introduces the Rorschach inkblot test.

1923 — Developmental psychologist Jean Piaget publishes *The Language and Thought of the Child.*

1924 — Mary Cover Jones reports reconditioning a fear reaction in a child (Peter), a forerunner of systematic desensitization developed by Joseph Wolpe.

1927 — In *Introduction to the Technique of Child Analysis,* Anna Freud discusses psychoanalysis in the treatment of children.

1929 — Wolfgang Köhler publishes *Gestalt Psychology,* which criticizes behaviorism and outlines essential elements of the gestalt theory.

1931 — 

Margaret Floy Washburn becomes the first female psychologist (and the second female scientist in any discipline) elected to the U.S. National Academy of Sciences.

Margaret Floy Washburn
(1871–1939)

1932 — In *The Wisdom of the Body,* Walter B. Cannon coins the term "homeostasis," discusses the fight-or-flight response, and identifies hormonal changes associated with stress.

1933 — 

Inez Beverly Prosser becomes the first Black woman to receive a Ph.D. degree in psychology from a U.S. institution (University of Cincinnati).

Inez Beverly Prosser
(1895–1934)

1934 — 

Ruth Winifred Howard becomes the second Black woman in the U.S. to receive a Ph.D. degree in psychology (University of Minnesota) and spends her career doing clinical work with children and young people.

Ruth Winifred Howard
(1900–1997)

1935 — Christiana Morgan and Henry Murray introduce the Thematic Apperception Test to elicit fantasies from people undergoing psychoanalysis.

1936 — Egas Moniz, a Portuguese physician, publishes work on the first frontal lobotomies performed on humans.

1938 — B. F. Skinner publishes *The Behavior of Organisms,* which describes operant conditioning of animals.

In *Primary Mental Abilities,* Louis L. Thurstone proposes seven such abilities.

Ugo Cerletti and Lucio Bini introduce electroshock treatment with a human patient.

1939 — David Wechsler publishes the Wechsler–Bellevue intelligence test, forerunner of the Wechsler Intelligence Scale for Children (WISC) and the Wechsler Adult Intelligence Scale (WAIS).

Mamie Phipps Clark receives a master's degree from Howard University. She later earns her doctorate and, with Kenneth B. Clark, provides joint research cited in the U.S. Supreme Court's 1954 decision to end racial segregation in public schools.

Mamie Phipps Clark
(1917–1983)

Edward Alexander Bott helps found the Canadian Psychological Association. He becomes its first president in 1940.

World War II provides many opportunities for psychologists to enhance the popularity and influence of psychology, especially in applied areas.

1941 — Raymond Cattell and John Horn distinguish fluid and crystallized intelligence. Decades later, John Carroll synthesizes these ideas as a bridge between a general intelligence factor (*g*) and specific abilities, to create the Cattell-Horn-Carroll (CHC) theory of intelligence.

1943 — Psychologist Starke Hathaway and physician J. Charnley McKinley publish the Minnesota Multiphasic Personality Inventory (MMPI).

1945 — 

Karen Horney, who criticized Freud's theory of female sexual development, publishes *Our Inner Conflicts.*

Karen Horney
(1885–1952)

All Portraits: Macmillan Learning

World War 2 provides many opportunities for psychologists to enhance the popularity and influence of psychology, especially in applied areas.

19 41: Raymond Cattell and John Horn distinguish fluid and crystallized intelligence. Decades later, John Carroll synthesizes these ideas as a bridge between a general intelligence factor (*g*) and

specific abilities, to create the Cattell-Horn-Carroll (C H C) theory of intelligence.

19 43: Psychologist Starke Hathaway and physician J. Charnley McKinley publish the *Minnesota Multiphasic Personality Inventory* (M M P I).

19 45: Karen Horney, who criticized Freud's theory of female sexual development, publishes *Our Inner Conflicts*. A portrait shows Karen Horney (18 85 to 19 52).

Return to History of psychology

Extended description for History of

psychology

1946 U.S. Congress creates the National Institute of Mental Health, making mental health a national priority.

Benjamin Spock's first edition of *The Commonsense Book of Baby and Child Care* appears; the book will influence child raising in North America for several decades.

1948 Alfred Kinsey and his colleagues publish *Sexual Behavior in the Human Male,* and they publish *Sexual Behavior in the Human Female* in **1953.**

B. F. Skinner's novel, *Walden Two,* describes a utopian community based on positive reinforcement, which becomes a clarion call for applying psychological principles in everyday living, especially communal living.

B. F. Skinner
(1904–1990)

Ernest R. Hilgard publishes *Theories of Learning,* which was required reading for several generations of psychology students in North America.

1949 Raymond B. Cattell publishes the Sixteen Personality Factor Questionnaire (16PF).

The scientist-practitioner model of training is approved at the Boulder Conference on Graduate Education in Clinical Psychology.

In *The Organization of Behavior: A Neuropsychological Theory,* Canadian psychologist Donald O. Hebb outlines a new and influential conceptualization of how the nervous system functions.

1950 Solomon Asch publishes studies of effects of conformity on judgments of line length.

In *Childhood and Society,* Erik Erikson outlines his stages of psychosocial development.

1951 Carl Rogers publishes *Client-Centered Therapy.*

1952 The American Psychiatric Association publishes the *Diagnostic and Statistical Manual of Mental Disorders,* an influential book that will be updated periodically.

1953 Eugene Aserinski and Nathaniel Kleitman describe rapid eye movements (REM) that occur during sleep.

Janet Taylor's Manifest Anxiety Scale appears in the *Journal of Abnormal Psychology.*

1954 In *Motivation and Personality,* Abraham Maslow proposes a hierarchy of motives ranging from physiological needs to self-actualization. (Maslow later updates the hierarchy to include self-transcendence needs.)

James Olds and Peter Milner, McGill University neuropsychologists, describe the rewarding effects of electrical stimulation of the hypothalamus in rats.

Gordon Allport publishes *The Nature of Prejudice.*

1956 In his *Psychological Review* article titled "The Magical Number Seven, Plus or Minus Two: Some Limits on Our Capacity for Processing Information," George Miller coins the term "chunk" for memory researchers.

1957 Robert Sears, Eleanor Maccoby, and Harry Levin publish *Patterns of Child Rearing.*

Charles Ferster and B. F. Skinner publish *Schedules of Reinforcement.*

1958 Harry Harlow publishes "The Nature of Love," outlining his work on attachment in monkeys.

1959 Noam Chomsky's critical review of B. F. Skinner's *Verbal Behavior* appears in the journal *Language.*

Keturah Whitehurst becomes the first Black person in the U.S. to be licensed as a psychologist. She later co-founds a human development and learning laboratory that provides educational opportunities to children in need.

Keturah Whitehurst
(1912–2000)

Eleanor Gibson and Richard Walk report their research on infants' depth perception in "The Visual Cliff."

Lloyd Peterson and Margaret Peterson, in the *Journal of Experimental Psychology* article, "Short-Term Retention of Individual Verbal Items," highlight the importance of rehearsal in memory.

John Thibaut and Harold Kelley publish *The Social Psychology of Groups.*

1960 George Sperling publishes "The Information Available in Brief Visual Presentations."

1961 Georg von Békésy receives a Nobel Prize for research on the physiology of hearing.

David McClelland publishes *The Achieving Society.*

1962 Jerome Kagan and Howard Moss publish *Birth to Maturity.*

Martha E. Bernal becomes the first Latina to earn a U.S. doctoral degree (Ph.D. in clinical psychology, Indiana University).

Martha E. Bernal
(1931–2001)

Stanley Schachter and Jerome Singer publish findings that support the two-factor theory of emotion.

Albert Ellis' *Reason and Emotion in Psychotherapy* is published; it is a milestone in the development of rational-emotive therapy (RET).

1963 Stanley Milgram's "Behavioral Study of Obedience" appears in the *Journal of Abnormal and Social Psychology.*

1964

Marigold Linton becomes the first Native American to receive a doctoral degree in psychology (University of California, Los Angeles). She is a founding member of both the Society for Advancement of Chicanos and Native Americans in Science, and the National Indian Education Association.

Marigold Linton
(born 1936)

1965 Canadian researcher Ronald Melzack and British researcher Patrick Wall propose the gate-control theory of pain.

The Archives of the History of American Psychology is founded at the University of Akron.

All Portraits: Macmillan Learning

Return to History of psychology

Extended description for History of

psychology

1966 Nancy Bayley becomes the first woman to receive the APA's Distinguished Scientific Contribution Award.

Jerome Bruner and colleagues at Harvard University's Center for Cognitive Studies publish *Studies in Cognitive Growth*.

William Masters and Virginia Johnson publish results of their research in *Human Sexual Responses*.

Allen Gardner and Beatrix Gardner begin training a chimpanzee named Washoe in American Sign Language at the University of Nevada, Reno. (Washoe dies in 2007.)

John Garcia
(1917–1983)

John Garcia and Robert Koelling publish a study on taste aversion in rats.

David M. Green and John A. Swets publish *Signal Detection Theory and Psychophysics*.

Julian Rotter publishes research on locus of control.

1967 Publication of Ulric Neisser's *Cognitive Psychology,* which helps to steer psychology away from behaviorism and toward cognitive processes.

Martin Seligman and Steven Maier publish the results of their research on "learned helplessness" in dogs.

1968 Richard Atkinson and Richard Shiffrin's influential three-stage memory model appears in *The Psychology of Learning and Motivation*.

Neal E. Miller's article in *Science,* describing instrumental conditioning of autonomic responses, stimulates research on biofeedback.

1969 Albert Bandura publishes *Principles of Behavior Modification*.

The Association for Women in Psychology is founded. E. Kitch Childs is instrumental in this effort, pioneering therapy techniques grounded in "intersectionality" (considering how race, class, and other aspects of identity may combine to create discrimination or disadvantage).

George Miller, in his APA presidential address, "Psychology as a Means of Promoting Human Welfare," emphasizes the importance of "giving psychology away."

1970 Psychologist Reiko Homma True lobbies successfully to open the Asian American Community Mental Health program—the first to focus on a minority population.

Reiko Homma True
(born 1933)

1971 

Kenneth B. Clark
(1914–2005)

Kenneth B. Clark becomes the first Black president of the APA. He spends his career studying racial bias in schools. His research helps desegregate U.S. schools and leads the federal government to prioritize spending to improve Black children's educational experiences.

Albert Bandura publishes *Social Learning Theory*.

B. F. Skinner publishes *Beyond Freedom and Dignity*.

1972 Elliot Aronson publishes *The Social Animal*.

Fergus Craik and Robert Lockhart's "Levels of Processing: A Framework for Memory Research" appears in the *Journal of Verbal Learning and Verbal Behavior*.

Robert Rescorla and Allan Wagner publish their associative model of Pavlovian conditioning.

Derald Wing Sue
(born 1942)

Stanley Sue
(born 1944)

Under the leadership of Derald Wing Sue and Stanley Sue, the Asian American Psychological Association is founded.

1973 APA votes to remove "homosexuality" as a psychological disorder from the *Diagnostic and Statistical Manual of Mental Disorders*.

Ethologists Karl von Frisch, Konrad Lorenz, and Nikolaas Tinbergen receive the Nobel Prize for their research on animal behavior.

1974 APA's Division 2 first publishes its journal, *Teaching of Psychology,* with Robert S. Daniel as editor.

Eleanor Maccoby and Carol Jacklin publish *The Psychology of Sex Differences*.

1975 Biologist Edward O. Wilson's *Sociobiology* is published; it will be a controversial precursor to evolutionary psychology.

1976 Sandra Wood Scarr and Richard A. Weinberg publish "IQ Test Performance of Black Children Adopted by White Families" in *American Psychologist*.

Robert V. Guthrie
(1930–2005)

Psychologist Robert V. Guthrie publishes *Even the Rat Was White,* the first history of Black psychologists in the U.S.

Saundra Murray Nettles chairs the Task Force on Black Women's Priorities, which leads to the creation of APA's Division 35, Section 1: The Psychology of Black Women.

Psychologist Carolyn Payton becomes Director of the U.S. Peace Corps, the first woman and the first Black person to serve in that role.

1978 Psychologist Herbert A. Simon, Carnegie-Mellon University, wins a Nobel Prize for pioneering research on computer simulations of human thinking and problem solving.

All Portraits: Macmillan Learning

His research helps desegregate U S schools and leads the federal government to prioritize spending to improve Black children's educational experiences. A portrait shows Kenneth B Clark (19 14 to 2005). Albert Bandura publishes *Social Learning Theory*. B F Skinner publishes *Beyond Freedom and Dignity*.

19 72: Elliot Aronson publishes *The Social Animal*. Fergus Craik and Robert Lockhart's "Levels of Processing: A Framework for Memory Research" appears in the *Journal of Verbal Learning and Verbal Behavior*. Robert Rescorla and Allan Wagner publish their

associative model of Pavlovian conditioning. Under the leadership of Derald Wing Sue and Stanley Sue, the Asian American Psychological Association is founded. Two portraits show Derald Wing Sue (born 19 42) and Stanley Sue (born 19 44).

19 73: A P A votes to remove homosexuality as a psychological disorder from the *Diagnostic and Statistical Manual of Mental Disorders*. Ethologists Karl von Frisch, Konrad Lorenz, and Nikolaas Tinbergen receive the Nobel Prize for their research on animal behavior.

19 74: A P A's Division 2 first publishes its journal, *Teaching of Psychology*, with Robert S Daniel as editor. Eleanor Maccoby and Carol Jacklin publish *The Psychology of Sex Differences*.

19 75: Biologist Edward O Wilson's *Sociobiology* is published; it will be a controversial precursor to evolutionary psychology.

19 76: Sandra Wood Scarr and Richard A. Weinberg publish "I Q Test Performance of Black Children Adopted by White Families" in *American Psychologist*. Psychologist Robert V Guthrie publishes *Even the Rat Was White*, the first history of Black psychologists in America. A portrait shows Robert V Guthrie (19 30 to 2005). Saundra Murray Nettles chairs the Task Force on Black Women's Priorities, which leads to the creation of A P A's Division 35, Section 1: The Psychology of Black Women. Psychologist Carolyn Payton becomes Director of

the U S Peace Corps, the first woman and the first Black person to serve in that role.

19 78: Psychologist Herbert A Simon, Carnegie-Mellon University, wins a Nobel Prize for pioneering research on computer simulations of human thinking and problem solving.

Return to History of psychology

Extended description for History of psychology

1979— James J. Gibson publishes *The Ecological Approach to Visual Perception.*

— Elizabeth Loftus publishes *Eyewitness Testimony,* showing that eyewitness memory is often inaccurate.

1981— David Hubel and Torsten Wiesel receive a Nobel Prize for research on single-cell recordings that identified feature detector cells in the visual cortex.

— Roger Sperry receives a Nobel Prize for research on split-brain patients.

— U.S. sociologist Harriette Pipe McAdoo publishes *Black Families,* an anthology of work done with John Lewis McAdoo on middle class Black families. Previous studies had focused on dysfunctional families, such as those in contact with prison and drug treatment programs.

— Paleontologist Stephen Jay Gould publishes *The Mismeasure of Man,* highlighting the debate concerning biological determination of intelligence.

1983— In his *Frames of Mind,* Howard Gardner outlines his theory of multiple intelligences.

1984— 44 Society for the Psychology of Sexual Orientation and Gender Diversity The APA creates Division 44 (Society for the Psychology of Sexual Orientation and Gender Diversity).

1987— Elizabeth Scarborough and Laurel Furumoto publish *Untold Lives: The First Generation of American Women Psychologists.*

— Fluoxetine (Prozac) is introduced as a treatment for depression.

— Wilbert J. McKeachie, University of Michigan, receives the first APA Award for Distinguished Career Contributions to Education and Training in Psychology.

1988— The American Psychological Society is founded. The organization changes its name to the Association for Psychological Science in **2006.**

1990— Psychiatrist Aaron Beck receives the Distinguished Scientific Award for the Applications of Psychology for advancing understanding and treatment of psychopathology, including pivotal contributions to the development of cognitive therapy.

— B. F. Skinner receives APA's first Citation for Outstanding Lifetime Contributions to Psychology and presents his last public address, "Can Psychology Be a Science of Mind?" (He died a few days later at age 86.)

1991— Martin Seligman publishes *Learned Optimism,* which foreshadows the "positive psychology" movement.

1992— Teachers of Psychology in Secondary Schools (TOPSS) is established as part of the APA.

— About 3000 U.S. secondary school students take the first Advanced Placement (AP) Examination in Psychology.

1993— Psychologist Judith Rodin is elected president of the University of Pennsylvania, becoming the first female president of an Ivy League school.

1996— Dorothy Cantor becomes the first president of the APA with a Psy.D. degree.

1998— *The Handbook of Asian American Psychology* is published.

2002— New Mexico becomes the first U.S. state to allow qualified clinical psychologists to prescribe certain drugs. Many U.S. states now allow nurse practitioners and other providers to prescribe psychiatric medication.

— Psychologist Daniel Kahneman, Princeton University, receives a Nobel Prize for research on decision making later summarized in his **2011** book, *Thinking Fast and Slow.*

2009— Psychologist Judy Chu becomes the first Chinese American woman elected to the U.S. Congress.

2011— Proposed by participants at the 2008 national conference at the University of Puget Sound, the document "Principles for Quality Undergraduate Education in Psychology," is approved as official APA policy.

— Melba J. T. Vasquez becomes the first Latina president of the APA.

Melba J. T. Vasquez
(born 1951)

2013— U.S. President Barack Obama announces $100 million in funding for an interdisciplinary project to advance understanding of the human brain.

2015— The *Independent Review Relating to APA Ethics Guidelines, National Security Interrogations, and Torture* is presented to the APA.

2018— Kristina Olson becomes the first psychologist to receive the National Science Foundation's Waterman Award. She also receives a 2018 MacArthur Fellowship for her work studying the social and cognitive development of transgender and gender-nonconforming youth.

2020— MacArthur Fellowship awardee and implicit bias researcher Jennifer L. Eberhardt receives multiple awards for authoring *Biased: Uncovering the Hidden Prejudice That Shapes What We See, Think, and Do.*

— Cognitive neuroscientist Damien Fair wins a MacArthur award for his work studying neurodiverse children.

2021— The APA issues an official "Apology to People of Color for APA's Role in Promoting, Perpetuating, and Failing to Challenge Racism, Racial Discrimination, and Human Hierarchy in the U.S."

All Portraits: Macmillan Learning

The timeline presents the following events:

19 79: James J Gibson publishes *The Ecological Approach to Visual Perception*. Elizabeth Loftus publishes *Eyewitness Testimony*, showing that eyewitness memory is often inaccurate.

19 81: David Hubel and Torsten Wiesel receive a Nobel Prize for research on single-cell recordings that identified feature detector cells in the visual cortex. Roger Sperry receives a Nobel Prize for research on split-brain patients. U S sociologist Harriette Pipe McAdoo publishes *Black Families*, an anthology of work done with John Lewis McAdoo on middle class Black families. Previous studies had focused on dysfunctional families, such as those in contact with prison and drug treatment programs. Paleontologist Stephen Jay Gould publishes *The Mismeasure of Man,* highlighting the debate concerning biological determination of intelligence.

19 83: In his *Frames of Mind,* Howard Gardner outlines his theory of multiple intelligences.

19 84: The A P A creates Division 44 (Society for the Psychology of Sexual Orientation and Gender Diversity). A logo reads, 44, Society for the Psychology of Sexual Orientation and Gender Diversity.

19 87: Elizabeth Scarborough and Laurel Furumoto publish *Untold Lives: The First Generation of American Women Psychologists*.

Fluoxetine (Prozac) is introduced as a treatment for depression. Wilbert J McKeachie, University of Michigan, receives the first A P A Award for Distinguished Career Contributions to Education and Training in Psychology.

19 88: The American Psychological Society is founded. It changes its name to Association for Psychological Science in 2006.

19 90: Psychiatrist Aaron Beck receives the Distinguished Scientific Award for the Applications of Psychology for advancing understanding and treatment of psychopathology, including pivotal contributions to the development of cognitive therapy. B F Skinner receives A P A's first Citation for Outstanding Lifetime Contributions to Psychology and presents his last public address, "Can Psychology Be a Science of Mind?" (He died a few days later at age 86.)

19 91: Martin Seligman publishes *Learned Optimism*, which foreshadows the "positive psychology" movement.

19 92: Teachers of Psychology in Secondary Schools (T O P S S) is established as part of the A P A. About 3,000 U S secondary school students take the first Advanced Placement (A P) Examination in Psychology.

19 93: Psychologist Judith Rodin is elected president of the University of Pennsylvania, becoming the first female president of an Ivy League school.

19 96: Dorothy Cantor becomes the first president of the A P A with a Psy D degree.

19 98: *The Handbook of Asian American Psychology* is published.

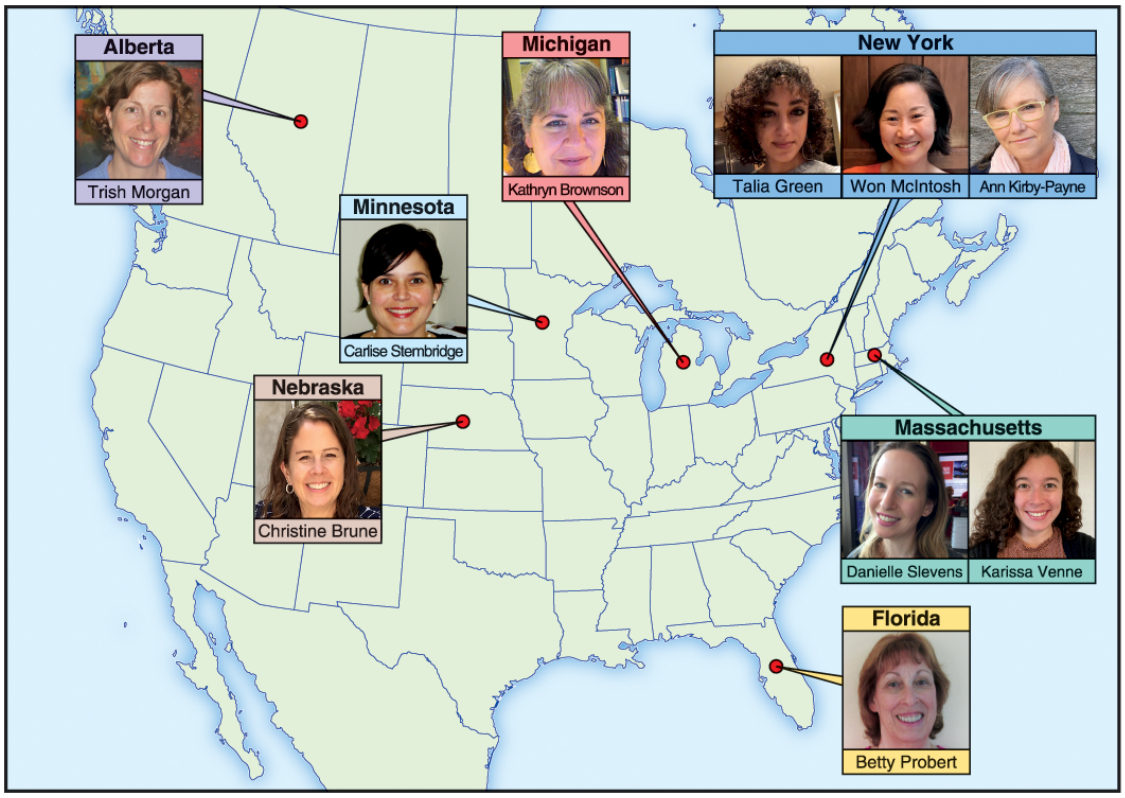
2002: New Mexico becomes the first U S state to allow qualified clinical psychologists to prescribe certain drugs. Many U S states now allow nurse practitioners and other providers to prescribe psychiatric medication. Psychologist Daniel Kahneman, Princeton University, receives a Nobel Prize for research on decision making later summarized in his 2011 book, *Thinking Fast and Slow*.

2009: Psychologist Judy Chu becomes the first Chinese-American woman elected to the U S Congress.

20 11: Proposed by participants at the 2008 national conference at the University of Puget Sound, the document, "Principles for Quality Undergraduate Education in Psychology" is approved as official A P A policy. Melba J T Vasquez is the first Latina president of the A P A. A photo shows Melba J T Vasquez (born 19 51).

2013: U S President Barack Obama announces 100 million dollars in funding for an interdisciplinary project to advance understanding of the human brain.

20 15: The *Independent Review Relating to A P A Ethics Guidelines, National Security Interrogations, and Torture* is presented to the A P A.



20 18: Kristina Olson becomes the first psychologist to receive the National Science Foundation's Waterman Award. She also receives a 2018 MacArthur Fellowship for her work studying the social and cognitive development of transgender and gender-nonconforming youth.

20 20: MacArthur Fellowship awardee and implicit bias researcher Jennifer L. Eberhardt receives multiple awards for authoring *Biased: Uncovering the Hidden Prejudice That Shapes What We See, Think and Do*. Cognitive neuroscientist Damien Fair wins a MacArthur award for his work studying neurodiverse children.

20 21: The A P A issues and official "Apology to People of Color For A P A's Role in Promoting, Perpetuating, and Failing to Challenge Racism, Racial Discrimination, and Human Hierarchy in the U S."

Extended description for FIGURE C.4 The human factor in accidents

The horizontal axis represents the Distance from runway in miles with values ranging from 20 to 0, in decrements of 2. The vertical axis represents Altitude in thousands of feet ranging from 0 to 10, in increments of 2. A line labeled Actual descent path starts at an altitude of 10 thousand feet in 20 miles distance from runway, drops to about 3 thousand feet at 14 miles, and then makes a drastic fall

close to 5 miles at 0 altitudes. A line labeled Pilot's perceived descent path starts at 10 thousand feet in 20 miles distance from runway and steeply drops to 0 miles at 0 altitude. An arrow pointing to the gap between the two curves is labeled, Altitude looks this much higher.

Logo: Achieve. The Achieve logo is at the top left of the page followed by text reading as follows.

ACHIEVE more this term!

Succeed in your course—and enjoy the experience!

We designed Achieve, in collaboration with students and faculty, on a foundation of learning research and rigorous testing. The result is a highly engaging, interactive, online learning experience with the power to adapt to your performance. *Psychology,* Fourteenth Edition, in Achieve will meet you where you are, and help you get to where you need to be!

A banner reads, **Achieve for Myers slash DeWall slash Gruber's *Psychology,* Fourteenth Edition, features:** This line is followed by six bullet points with text reading as follows.

LearningCurve Adaptive Quizzing: Students tell us they love this time-tested, game-oriented resource that helps them prepare for class and do better in the course.

Mobile-Ready, Fully Accessible, Interactive E-book: With built-in self-tests, you will know what you know, and retain what you need. The e-book also offers note-taking, highlighting, and search functions.

Goal Setting and Reflection Surveys will help guide you, and will help you connect with your instructor to get the support you need.

Skills for Student Success—How to Apply Psychology to Live Your Best Life: This interactive feature, which accompanies the Student Preface in the text/e-book, will help you get the right start in this course and in college with five helpful sections: Thinking Critically and Scientifically, Self-Control and Self-Improvement, Time Management and Study Tips, Social Life (including the section Embrace Diversity), and Finding Meaning and Pursuing Goals.

Immersive Learning Activities: In the ***How Would You Know?*** research activities, you play the role of researcher, making choices about the best ways to test interesting questions, such as *How Would You Know If a Cup of Coffee Can Warm Up Relationships?* In the ***Assess Your Strengths*** activities, you will apply what you're learning to your own life and experiences by assessing yourself on a "strength" (quality of sleep, relationship strength, emotional diversity, awe experiences, and more), then get tips for nurturing that strength in your own life.

Video Collection for Introductory Psychology: These brief, engaging videos will help you learn about classic as well as current concepts, such as the emotional toll of the Covid-19 pandemic, the effects of the Black Lives Matter movement, video game addiction, issues related to transgender youth, and race and racial bias.
